# About this Guide

This HDL guide is part of the ISE documentation collection. A separate version of this guide is available if you prefer to work with schematics.

This guide contains the following:

- Introduction.
- A list of design elements supported in this architecture, organized by functional categories.
- Individual descriptions of each available primitive.

## About Design Elements

This version of the Libraries Guide describes the primitives that comprise the Xilinx Unified Libraries for this architecture, and includes examples of instantiation code for each element.

Primitives are Xilinx components that are native to the FPGA you are targeting. If you instantiate a primitive in your design, after the translation process you will end up with the exact same component in the back end. For example, if you instantiate the Virtex-5 element known as `ISERDES_NODELAY` as a user primitive, after you run translate (`ngdbuild`) you will end up with an `ISERDES_NODELAY` in the back end as well. If you were using `ISERDES` in a Virtex-5 device, then this will automatically retarget to an `ISERDES_NODELAY` for Virtex-5 in the back end. Hence, this concept of a “primitive” differs from other uses of that term in this technology.

Xilinx maintains software libraries with hundreds of functional design elements (unimacros and primitives) for different device architectures. New functional elements are assembled with each release of development system software. In addition to a comprehensive Unified Library containing all design elements, beginning in 2003, Xilinx developed a separate library for each architecture. This guide is one in a series of architecture-specific libraries.

## Design Entry Methods

For each design element in this guide, Xilinx evaluates the four options and recommends what we believe is the best solution for you. The four options are:

- **Instantiation** - This component can be instantiated directly into the design. This method is useful if you want to control the exact placement of the individual blocks.
- **Inference** - This component can be inferred by most supported synthesis tools. You should use this method if you want to have complete flexibility and portability of the code to multiple architectures. Inference also gives the tools the ability to optimize for performance, area, or power, as specified by the user to the synthesis tool.
- **Coregen & Wizards** - This component can be used through Coregen or Wizards. You should use this method if you want to build large blocks of any FPGA primitive that cannot be inferred. When using this flow, you will have to re-generate your cores for each architecture that you are targeting.
- **Macro Support** - This component has a UniMacro that can be used. These components are in the UniMacro library in the Xilinx tool, and are used to instantiate primitives that are complex to instantiate by just using the primitives. The synthesis tools will automatically expand the unimacros to their underlying primitives.

# Functional Categories

This section categorizes, by function, the circuit design elements described in detail later in this guide. The elements (*primitives* and *macros*) are listed in alphanumeric order under each functional category.

Arithmetic Functions

I/O Components

Shift Register LUT

Clock Components

RAM/ROM

Slice/CLB Primitives

Config/BSCAN Components

Registers & Latches

## Arithmetic Functions

Design Element	Description
MULT18X18	Primitive: 18 x 18 Signed Multiplier
MULT18X18S	Primitive: 18 x 18 Signed Multiplier -- Registered Version

## Clock Components

Design Element	Description
BUFG	Primitive: Global Clock Buffer
BUFGCE	Primitive: Global Clock Buffer with Clock Enable
BUFGCE_1	Primitive: Global Clock Buffer with Clock Enable and Output State 1
BUFGMUX	Primitive: Global Clock MUX Buffer
BUFGMUX_1	Primitive: Global Clock MUX Buffer with Output State 1
CLKDLL	Primitive: Clock Delay Locked Loop
CLKDLE	Primitive: Clock Delay Locked Loop with Expanded Output
CLKDLLHF	Primitive: High Frequency Clock Delay Locked Loop
DCM	Primitive: Digital Clock Manager
IBUFG	Primitive: Dedicated Input Clock Buffer
IBUFGDS	Primitive: Differential Signaling Dedicated Input Clock Buffer and Optional Delay

## Config/BSCAN Components

Design Element	Description
BSCAN_VIRTEX2	Primitive: Virtex2 Boundary Scan Logic Control Circuit
CAPTURE_VIRTEX2	Primitive: Virtex4 Register State Capture for Bitstream Readback
ICAP_VIRTEX2	Primitive: User Interface to Virtex-II Internal Configuration Access Port
STARTUP_VIRTEX2	Primitive: Virtex-II, Virtex-II Pro, and Virtex-II User Interface to Global Clock, Reset, and 3-State Controls

## I/O Components

Design Element	Description
IBUF	Primitive: Input Buffer
IBUFDS	Primitive: Differential Signaling Input Buffer with Optional Delay
IBUFG	Primitive: Dedicated Input Clock Buffer
IBUFGDS	Primitive: Differential Signaling Dedicated Input Clock Buffer and Optional Delay
IOBUF	Primitive: Bi-Directional Buffer
IOBUFDS	Primitive: 3-State Differential Signaling I/O Buffer with Active Low Output Enable
KEEPER	Primitive: KEEPER Symbol
OBUF	Primitive: Output Buffer
OBUFDS	Primitive: Differential Signaling Output Buffer
OBUFFT	Primitive: 3-State Output Buffer with Active Low Output Enable
OBUFFTDS	Primitive: 3-State Output Buffer with Differential Signaling, Active-Low Output Enable
PULLDOWN	Primitive: Resistor to GND for Input Pads, Open-Drain, and 3-State Outputs
PULLUP	Primitive: Resistor to VCC for Input PADS, Open-Drain, and 3-State Outputs

## RAM/ROM

Design Element	Description
RAM128X1S	Primitive: 128-Deep by 1-Wide Static Synchronous RAM
RAM128X1S_1	Primitive: 128-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock
RAM16X1D	Primitive: 16-Deep by 1-Wide Static Dual Port Synchronous RAM
RAM16X1D_1	Primitive: 16-Deep by 1-Wide Static Dual Port Synchronous RAM with Negative-Edge Clock
RAM16X1S	Primitive: 16-Deep by 1-Wide Static Synchronous RAM
RAM16X1S_1	Primitive: 16-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock
RAM16X2S	Primitive: 16-Deep by 2-Wide Static Synchronous RAM
RAM16X4S	Primitive: 16-Deep by 4-Wide Static Synchronous RAM
RAM16X8S	Primitive: 16-Deep by 8-Wide Static Synchronous RAM
RAM32X1D	Primitive: 32-Deep by 1-Wide Static Dual Port Synchronous RAM
RAM32X1D_1	Primitive: 32-Deep by 1-Wide Static Dual Port Synchronous RAM with Negative-Edge Clock
RAM32X1S	Primitive: 32-Deep by 1-Wide Static Synchronous RAM
RAM32X1S_1	Primitive: 32-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock
RAM32X2S	Primitive: 32-Deep by 2-Wide Static Synchronous RAM
RAM32X4S	Primitive: 32-Deep by 4-Wide Static Synchronous RAM
RAM32X8S	Primitive: 32-Deep by 8-Wide Static Synchronous RAM
RAM64X1D	Primitive: 64-Deep by 1-Wide Dual Port Static Synchronous RAM

Design Element	Description
<a href="#">RAM64X1D_1</a>	Primitive: 64-Deep by 1-Wide Dual Port Static Synchronous RAM with Negative-Edge Clock
<a href="#">RAM64X1S</a>	Primitive: 64-Deep by 1-Wide Static Synchronous RAM
<a href="#">RAM64X1S_1</a>	Primitive: 64-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock
<a href="#">RAM64X2S</a>	Primitive: 64-Deep by 2-Wide Static Synchronous RAM
<a href="#">RAMB16_S1</a>	Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 1-bit Port
<a href="#">RAMB16_S1_S1</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit Ports
<a href="#">RAMB16_S1_S18</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 18-bit Ports
<a href="#">RAMB16_S1_S2</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 2-bit Ports
<a href="#">RAMB16_S1_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 36-bit Ports
<a href="#">RAMB16_S1_S4</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 4-bit Ports
<a href="#">RAMB16_S1_S9</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 9-bit Ports
<a href="#">RAMB16_S18</a>	Primitive: 16K-bit Data + 2K-bit Parity Memory, Single-Port Synchronous Block RAM with 18-bit Port
<a href="#">RAMB16_S18_S18</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 18-bit Ports
<a href="#">RAMB16_S18_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 18-bit and 36-bit Ports
<a href="#">RAMB16_S2</a>	Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 2-bit Port
<a href="#">RAMB16_S2_S2</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit Ports
<a href="#">RAMB16_S2_S18</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 18-bit Ports
<a href="#">RAMB16_S2_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 36-bit Ports
<a href="#">RAMB16_S2_S4</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 4-bit Ports
<a href="#">RAMB16_S2_S9</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 9-bit Ports
<a href="#">RAMB16_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 36-bit Port
<a href="#">RAMB16_S36_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with Two 36-bit Ports
<a href="#">RAMB16_S4</a>	Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 4-bit Port
<a href="#">RAMB16_S4_S18</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 18-bit Ports
<a href="#">RAMB16_S4_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 36-bit Ports

Design Element	Description
<a href="#">RAMB16_S4_S4</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit Ports
<a href="#">RAMB16_S4_S9</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 9-bit Ports
<a href="#">RAMB16_S9</a>	Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 9-bit Port
<a href="#">RAMB16_S9_S18</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit and 18-bit Ports
<a href="#">RAMB16_S9_S36</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit and 36-bit Ports
<a href="#">RAMB16_S9_S9</a>	Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit Ports
<a href="#">RAMB4_S1</a>	Primitive: 4K-bit Single-Port Synchronous Block RAM with Port Width Configured to 1 Bit
<a href="#">RAMB4_S1_S1</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit
<a href="#">RAMB4_S1_S16</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 16-bits
<a href="#">RAMB4_S1_S2</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 2-bits
<a href="#">RAMB4_S1_S4</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 4-bits
<a href="#">RAMB4_S1_S8</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 8-bits
<a href="#">RAMB4_S16</a>	Primitive: 4096-Bit Single-Port Synchronous Block RAM with Port Width Configured to 16 Bits
<a href="#">RAMB4_S16_S16</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 16-bits
<a href="#">RAMB4_S2</a>	Primitive: 4K-bit Single-Port Synchronous Block RAM with Port Width Configured to 2-bits
<a href="#">RAMB4_S2_S16</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 16-bits
<a href="#">RAMB4_S2_S2</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 2-bits
<a href="#">RAMB4_S2_S4</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 4-bits
<a href="#">RAMB4_S2_S8</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 8-bits
<a href="#">RAMB4_S4</a>	Primitive: 4k-bit Single-Port Synchronous Block RAM with Port Width Configured to 4-bits
<a href="#">RAMB4_S4_S16</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 16-bits
<a href="#">RAMB4_S4_S4</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 4-bits
<a href="#">RAMB4_S4_S8</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 8-bits
<a href="#">RAMB4_S8</a>	Primitive: 4k-bit Single-Port Synchronous Block RAM with Port Width Configured to 8-bits

Design Element	Description
<a href="#">RAMB4_S8_S16</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 8-bits and 16-bits
<a href="#">RAMB4_S8_S8</a>	Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 8-bits
<a href="#">ROM128X1</a>	Primitive: 128-Deep by 1-Wide ROM
<a href="#">ROM16X1</a>	Primitive: 16-Deep by 1-Wide ROM
<a href="#">ROM256X1</a>	Primitive: 256-Deep by 1-Wide ROM
<a href="#">ROM32X1</a>	Primitive: 32-Deep by 1-Wide ROM
<a href="#">ROM64X1</a>	Primitive: 64-Deep by 1-Wide ROM

## Registers & Latches

Design Element	Description
<a href="#">FDCE</a>	Primitive: D Flip-Flop with Clock Enable and Asynchronous Clear
<a href="#">FDCE_1</a>	Primitive: D Flip-Flop with Negative-Edge Clock, Clock Enable, and Asynchronous Clear
<a href="#">FDCPE</a>	Primitive: D Flip-Flop with Clock Enable and Asynchronous Preset and Clear
<a href="#">FDCPE_1</a>	Primitive: D Flip-Flop with Negative-Edge Clock, Clock Enable, and Asynchronous Preset and Clear
<a href="#">FDRSE</a>	Primitive: D Flip-Flop with Synchronous Reset and Set and Clock Enable
<a href="#">FDRSE_1</a>	Primitive: D Flip-Flop with Negative-Clock Edge, Synchronous Reset and Set, and Clock Enable
<a href="#">IFDDRCPE</a>	Primitive: Dual Data Rate Input D Flip-Flop with Clock Enable and Asynchronous Preset and Clear
<a href="#">IFDDRRSE</a>	Primitive: Dual Data Rate Input D Flip-Flop with Synchronous Reset and Set and Clock Enable
<a href="#">LDCPE</a>	Primitive: Transparent Data Latch with Asynchronous Clear and Preset and Gate Enable
<a href="#">OFDDRCPE</a>	Primitive: Dual Data Rate Output D Flip-Flop with Clock Enable and Asynchronous Preset and Clear
<a href="#">OFDDRRSE</a>	Primitive: Dual Data Rate Output D Flip-Flop with Synchronous Reset and Set and Clock Enable
<a href="#">OFDDRTCPE</a>	Primitive: Dual Data Rate D Flip-Flop with Active-Low 3--State Output Buffer, Clock Enable, and Asynchronous Preset and Clear
<a href="#">OFDDRTRSE</a>	Primitive: Dual Data Rate D Flip-Flop with Active -Low 3-State Output Buffer, Synchronous Reset and Set, and Clock Enable

## Shift Register LUT

Design Element	Description
<a href="#">SRL16</a>	Primitive: 16-Bit Shift Register Look-Up-Table (LUT)
<a href="#">SRL16_1</a>	Primitive: 16-Bit Shift Register Look-Up-Table (LUT) with Negative-Edge Clock

Design Element	Description
SRL16E	Primitive: 16-Bit Shift Register Look-Up-Table (LUT) with Clock Enable
SRL16E_1	Primitive: 16-Bit Shift Register Look-Up-Table (LUT) with Negative-Edge Clock and Clock Enable
SRLC16	Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry
SRLC16_1	Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry and Negative-Edge Clock
SRLC16E	Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry and Clock Enable
SRLC16E_1	Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry, Negative-Edge Clock, and Clock Enable

## Slice/CLB Primitives

Design Element	Description
BUFCF	Primitive: Fast Connect Buffer
LUT1	Primitive: 1-Bit Look-Up-Table with General Output
LUT1_D	Primitive: 1-Bit Look-Up-Table with Dual Output
LUT1_L	Primitive: 1-Bit Look-Up-Table with Local Output
LUT2	Primitive: 2-Bit Look-Up-Table with General Output
LUT2_D	Primitive: 2-Bit Look-Up-Table with Dual Output
LUT2_L	Primitive: 2-Bit Look-Up-Table with Local Output
LUT3	Primitive: 3-Bit Look-Up-Table with General Output
LUT3_D	Primitive: 3-Bit Look-Up-Table with Dual Output
LUT3_L	Primitive: 3-Bit Look-Up-Table with Local Output
LUT4	Primitive: 4-Bit Look-Up-Table with General Output
LUT4_D	Primitive: 4-Bit Look-Up-Table with Dual Output
LUT4_L	Primitive: 4-Bit Look-Up-Table with Local Output
MULT_AND	Primitive: Fast Multiplier AND
MUXCY	Primitive: 2-to-1 Multiplexer for Carry Logic with General Output
MUXCY_D	Primitive: 2-to-1 Multiplexer for Carry Logic with Dual Output
MUXCY_L	Primitive: 2-to-1 Multiplexer for Carry Logic with Local Output
MUXF5	Primitive: 2-to-1 Look-Up Table Multiplexer with General Output
MUXF5_D	Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output
MUXF5_L	Primitive: 2-to-1 Look-Up Table Multiplexer with Local Output
MUXF6	Primitive: 2-to-1 Look-Up Table Multiplexer with General Output
MUXF6_D	Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output
MUXF6_L	Primitive: 2-to-1 Look-Up Table Multiplexer with Local Output
MUXF7	Primitive: 2-to-1 Look-Up Table Multiplexer with General Output
MUXF7_D	Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output
MUXF7_L	Primitive: 2-to-1 Look-Up Table Multiplexer with Local Output

---

Design Element	Description
<a href="#">MUXF8</a>	Primitive: 2-to-1 Look-Up Table Multiplexer with General Output
<a href="#">MUXF8_D</a>	Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output

# About Design Elements

This section describes the design elements that can be used with this architecture. The design elements are organized alphabetically.

The following information is provided for each design element, where applicable:

- Name of element
- Brief description
- Schematic symbol (if any)
- Logic table (if any)
- Port descriptions
- Design Entry Method
- Available attributes (if any)
- Example instantiation code
- For more information

# BSCAN\_VIRTEX2

Primitive: Virtex2 Boundary Scan Logic Control Circuit

## Introduction

This design element provides access to the BSCAN sites on a Virtex-II, Virtex-II Pro, or Virtex-II Pro X device. It is used to create internal boundary scan chains. The 4-pin JTAG interface (TDI, TDO, TCK, and TMS) are dedicated pins in Virtex-II, Virtex-II Pro, and Virtex-II Pro X. To use normal JTAG for boundary scan purposes, just hook up the JTAG pins to the port and go. The pins on the this design element do not need to be connected, unless those special functions are needed to drive an internal scan chain.

A signal on the TDO1 input is passed to the external TDO output when the USER1 instruction is executed; the SEL1 output goes High to indicate that the USER1 instruction is active. The DRCK1 output provides USER1 access to the data register clock (generated by the TAP controller). The TDO2 and SEL2 pins perform a similar function for the USER2 instruction and the DRCK2 output provides USER2 access to the data register clock (generated by the TAP controller). The RESET, UPDATE, SHIFT, and CAPTURE pins represent the decoding of the corresponding state of the boundary scan internal state machine. The TDI pin provides access to the TDI signal of the JTAG port in order to shift data into an internal scan chain.

**Note** For specific information on boundary scan for an architecture, see *The Programmable Logic Data Sheets*

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- BSCAN_VIRTEX2: Boundary Scan primitive for connecting internal logic to
--                JTAG interface. Virtex-II/II-Pro
-- Xilinx HDL Libraries Guide, version 10.1.2
```

```

BSCAN_VIRTEX2_inst : BSCAN_VIRTEX2
port map (
CAPTURE => CAPTURE, -- CAPTURE output from TAP controller
DRCK1 => DRCK1,     -- Data register output for USER1 functions
DRCK2 => DRCK2,     -- Data register output for USER2 functions
RESET => RESET,     -- Reset output from TAP controller
SEL1 => SEL1,       -- USER1 active output
SEL2 => SEL2,       -- USER2 active output
SHIFT => SHIFT,    -- SHIFT output from TAP controller
TDI => TDI,        -- TDI output from TAP controller
UPDATE => UPDATE,  -- UPDATE output from TAP controller
TDO1 => TDO1,      -- Data input for USER1 function
TDO2 => TDO2       -- Data input for USER2 function
);

-- End of BSCAN_VIRTEX2_inst instantiation

```

## Verilog Instantiation Template

```

// BSCAN_VIRTEX2: Boundary Scan primitive for connecting internal logic to
//                JTAG interface. Virtex-II/II-Pro
// Xilinx HDL Libraries Guide, version 10.1.2

BSCAN_VIRTEX2 BSCAN_VIRTEX2_inst (
.CAPTURE(CAPTURE), // CAPTURE output from TAP controller
.DRCK1(DRCK1),     // Data register output for USER1 functions
.DRCK2(DRCK2),     // Data register output for USER2 functions
.RESET(RESET),     // Reset output from TAP controller
.SEL1(SEL1),       // USER1 active output
.SEL2(SEL2),       // USER2 active output
.SHIFT(SHIFT),     // SHIFT output from TAP controller
.TDI(TDI),        // TDI output from TAP controller
.UPDATE(UPDATE),  // UPDATE output from TAP controller
.TDO1(TDO1),      // Data input for USER1 function
.TDO2(TDO2)       // Data input for USER2 function
);

// End of BSCAN_VIRTEX2_inst instantiation

```

# BUFCF

Primitive: Fast Connect Buffer

## Introduction

This design element is a single fast connect buffer used to connect the outputs of the LUTs and some dedicated logic directly to the input of another LUT. Using this buffer implies CLB packing. No more than four LUTs may be connected together as a group.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFCF: Fast connect buffer used to connect the outputs of the LUTs
--       and some dedicated logic directly to the input of another LUT.
--       For use with all FPGAs.
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFCF_inst: BUFCF (
port map (
O => O, -- Connect to the output of a LUT
I => I -- Connect to the input of a LUT
);

-- End of BUFCF_inst instantiation
```

## Verilog Instantiation Template

```
// BUFCF: Fast connect buffer used to connect the outputs of the LUTs
//       and some dedicated logic directly to the input of another LUT.
//       For use with all FPGAs.
// Xilinx HDL Libraries Guide, version 10.1.2

BUFCF BUFCF_inst (
.O(O), // Connect to the output of a LUT
.I(I) // Connect to the input of a LUT
);

// End of BUFCF_inst instantiation
```

---

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# BUFG

Primitive: Global Clock Buffer

## Introduction

This design element is a high-fanout buffer that connects signals to the global routing resources for low skew distribution of the signal. BUFGs are typically used on clock nets as well other high fanout nets like sets/resets and clock enables.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFG: Global Clock Buffer (source by an internal signal)
-- All Devices
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFG_inst : BUFG
port map (
O => O,      -- Clock buffer output
I => I       -- Clock buffer input
);

-- End of BUFG_inst instantiation
```

## Verilog Instantiation Template

```
// BUFG: Global Clock Buffer (source by an internal signal)
// All FPGAs
// Xilinx HDL Libraries Guide, version 10.1.2

BUFG BUFG_inst (
.O(O),      // Clock buffer output
.I(I)       // Clock buffer input
);

// End of BUFG_inst instantiation
```

---

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# BUFGCE

Primitive: Global Clock Buffer with Clock Enable

## Introduction

This design element is a global clock buffer with a single gated input. Its O output is "0" when clock enable (CE) is Low (inactive). When clock enable (CE) is High, the I input is transferred to the O output.

## Logic Table

Inputs		Outputs
I	CE	O
X	0	0
I	1	I

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFGCE: Global Clock Buffer with Clock Enable (active high)
--           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFGCE_inst : BUFGCE
port map (
O => O, -- Clock buffer ouputput
CE => CE, -- Clock enable input
I => I -- Clock buffer input
);

-- End of BUFGCE_inst instantiation
    
```

## Verilog Instantiation Template

```
// BUFGCE: Global Clock Buffer with Clock Enable (active high)
//           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

BUFGCE BUFGCE_inst (
.O(O), // Clock buffer output
.CE(CE), // Clock enable input
.I(I) // Clock buffer input
);

// End of BUFGCE_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# BUFGCE\_1

Primitive: Global Clock Buffer with Clock Enable and Output State 1

## Introduction

This design element is a multiplexed global clock buffer with a single gated input. Its O output is High (1) when clock enable (CE) is Low (inactive). When clock enable (CE) is High, the I input is transferred to the O output.

## Logic Table

Inputs		Outputs
I	CE	O
X	0	1
I	1	I

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFGCE_1: Global Clock Buffer with Clock Enable (active low)
--           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFGCE_1_inst : BUFGCE_1
port map (
O => O, -- Clock buffer ouputput
CE => CE, -- Clock enable input
I => I -- Clock buffer input
);

-- End of BUFGCE_1_inst instantiation
    
```

## Verilog Instantiation Template

```
// BUFGCE_1: Global Clock Buffer with Clock Enable (active low)
//           Virtex-II/II-Pro, Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

BUFGCE_1 BUFGCE_1_inst (
.O(O), // Clock buffer output
.CE(CE), // Clock enable input
.I(I) // Clock buffer input
);

// End of BUFGCE_1_inst instantiation
```

## For More Information

- See the [Virtex-II Data Sheets](#).

# BUFGMUX

Primitive: Global Clock MUX Buffer

## Introduction

BUFGMUX is a multiplexed global clock buffer, based off of the BUFGCTRL, that can select between two input clocks: I0 and I1. When the select input (S) is Low, the signal on I0 is selected for output (O). When the select input (S) is High, the signal on I1 is selected for output.

BUFGMUX and BUFGMUX\_1 are distinguished by the state the output assumes when that output switches between clocks in response to a change in its select input. BUFGMUX assumes output state 0 and BUFGMUX\_1 assumes output state 1.

**Note** BUFGMUX guarantees that when S is toggled, the state of the output remains in the inactive state until the next active clock edge (either I0 or I1) occurs.

## Logic Table

Inputs			Outputs
I0	I1	S	O
I0	X	0	I0
X	I1	1	I1
X	X	↑	0
X	X	↓	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFGMUX: Global Clock Buffer 2-to-1 MUX
--           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFGMUX_inst : BUFGMUX
port map (
O => O,      -- Clock MUX output
    
```

```
I0 => I0, -- Clock0 input
I1 => I1, -- Clock1 input
S => S    -- Clock select input
);

-- End of BUFGMUX_inst instantiation
```

## Verilog Instantiation Template

```
// BUFGMUX: Global Clock Buffer 2-to-1 MUX
//           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

BUFGMUX BUFGMUX_inst (
.O(O),    // Clock MUX output
.I0(I0),  // Clock0 input
.I1(I1),  // Clock1 input
.S(S)     // Clock select input
);

// End of BUFGMUX_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# BUFGMUX\_1

Primitive: Global Clock MUX Buffer with Output State 1

## Introduction

This design element is a multiplexed global clock buffer that can select between two input clocks: I0 and I1. When the select input (S) is Low, the signal on I0 is selected for output (O). When the select input (S) is High, the signal on I1 is selected for output.

This design element is distinguished from BUFGMUX by the state the output assumes when that output switches between clocks in response to a change in its select input. BUFGMUX assumes output state 0 and BUFGMUX\_1 assumes output state 1.

## Logic Table

Inputs			Outputs
I0	I1	S	O
I0	X	0	I0
X	I1	1	I1
X	X	↑	1
X	X	↓	1

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- BUFGMUX_1: Global Clock Buffer 2-to-1 MUX (inverted select)
--           Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

BUFGMUX_1_inst : BUFGMUX_1
port map (
O => O,    -- Clock MUX output
I0 => I0,  -- Clock0 input
I1 => I1,  -- Clock1 input
S => S     -- Clock select input

```

```
);  
-- End of BUFGMUX_1_inst instantiation
```

## Verilog Instantiation Template

```
// BUFGMUX_1: Global Clock Buffer 2-to-1 MUX (inverted select)  
//           Virtex-II/II-Pro, Spartan-3/3E/3A  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
BUFGMUX_1 BUFGMUX_1_inst (  
  .O(O), // Clock MUX output  
  .I0(I0), // Clock0 input  
  .I1(I1), // Clock1 input  
  .S(S) // Clock select input  
);  
  
// End of BUFGMUX_1_inst instantiation
```

## For More Information

- See the [Virtex-II Data Sheets](#).

# CAPTURE\_VIRTEX2

Primitive: Virtex4 Register State Capture for Bitstream Readback

## Introduction

This element provides user control and synchronization over when and how the capture register (flip-flop and latch) information task is requested. The readback function is provided through dedicated configuration port instructions. However, without this element, the readback data is synchronized to the configuration clock. Only register (flip-flop and latch) states can be captured. Although LUT RAM, SRL, and block RAM states are readback, they cannot be captured.

An asserted high CAP signal indicates that the registers in the device are to be captured at the next Low-to-High clock transition. By default, data is captured after every trigger when transition on CLK while CAP is asserted. To limit the readback operation to a single data capture, add the ONESHOT=TRUE attribute to this element.

## Port Descriptions

Port	Direction	Width	Function
CAP	Input	1	Readback capture trigger
CLK	Input	1	Readback capture clock

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

Connect all inputs and outputs to the design in order to ensure proper operation.

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
ONESHOT	Boolean	TRUE, FALSE	TRUE	Specifies the procedure for performing single readback per CAP trigger.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- CAPTURE_VIRTEX2: Register State Capture for Bitstream Readback
--                               Virtex-II/II-Pro
-- Xilinx HDL Libraries Guide, version 10.1.2

CAPTURE_VIRTEX2_inst : CAPTURE_VIRTEX2
port map (
CAP => CAP,    -- Capture input
CLK => CLK     -- Clock input
);

-- End of CAPTURE_VIRTEX2_inst instantiation
```

## Verilog Instantiation Template

```
// CAPTURE_VIRTEX2: Register State Capture for Bitstream Readback
//                               Virtex-II/II-Pro
// Xilinx HDL Libraries Guide, version 10.1.2

CAPTURE_VIRTEX2 CAPTURE_VIRTEX2_inst (
.CAP(CAP),    // Capture input
.CLK(CLK)    // Clock input
);

// End of CAPTURE_VIRTEX2_inst instantiation
```

## For More Information

# CLKDLL

Primitive: Clock Delay Locked Loop

## Introduction

This design element is a clock delay locked loop used to minimize clock skew. It synchronizes the clock signal at the feedback clock input (CLKFB) to the clock signal at the input clock (CLKIN). The locked output (LOCKED) is high when the two signals are in phase. The signals are considered to be in phase when their rising edges are within a specific range of each other (see The Programmable Logic Data Sheets for the most current value).

The frequency of the clock signal at the CLKIN input must be in a specific range depending on speed grade (see The Programmable Logic Data Sheets for the most current values). The CLKIN pin must be driven by an IBUFG or a BUFG. If phase alignment is not required, CLKIN can also be driven by IBUF.

On-chip synchronization is achieved by connecting the CLKFB input to a point on the global clock network driven by a BUFG, a global clock buffer. The BUFG connected to the CLKFB input of the CLKDLL must be sourced from either the CLK0 or CLK2X outputs of the same CLKDLL. The CLKIN input should be connected to the output of an IBUFG, with the IBUFG input connected to a pad driven by the system clock.

Off-chip synchronization is achieved by connecting the CLKFB input to the output of an IBUFG, with the IBUFG input connected to a pad. Either the CLK0 or CLK2X output can be used but not both. The CLK0 or CLK2X must be connected to the input of OBUF, an output buffer.

The duty cycle of the CLK0 output is 50-50 unless the DUTY\_CYCLE\_CORRECTION attribute is set to FALSE, in which case the duty cycle is the same as that of the CLKIN input. The duty cycle of the phase shifted outputs (CLK90, CLK180, and CLK270) is the same as that of the CLK0 output. The duty cycle of the CLK2X and CLKDV outputs is always 50-50. The frequency of the CLKDV output is determined by the value assigned to the CLKDV\_DIVIDE attribute.

The master reset input (RST) resets CLKDLL to its initial (power-on) state. The signal at the RST input is asynchronous and must be held High for just 2ns.

## Port Descriptions

Port	Function
CLK0	Clock at 1x CLKIN frequency
CLK180	Clock at 1x CLKIN frequency, shifted 180° with regards to CLK0
CLK270	Clock at 1x CLKIN frequency, shifted 270° with regards to CLK0
CLK2X	Clock at 2x CLKIN frequency, in phase with CLK0
CLK90	Clock at 1x CLKIN frequency, shifted 90° with regards to CLK0
CLKDV	Clock at (1/n)x CLKIN frequency, n=CLKDV_DIVIDE value. CLKDV is in phase with CLK0.
LOCKED	CLKDLL locked

**Note** See the "PERIOD Specifications on CLKDLLs and DCM" in the *Constraints Guide* for additional information on using the TNM, TNM\_NET, and PERIOD attributes with CLKDLL components.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;

# CLKDLLE

Primitive: Clock Delay Locked Loop with Expanded Output

## Introduction

This design element is a clock delay locked loop used to minimize clock skew. It synchronizes the clock signal at the feedback clock input (CLKFB) to the clock signal at the input clock (CLKIN). The locked output (LOCKED) is high when the two signals are in phase. The signals are considered to be in phase when their rising edges are within a specific range of each other (see The Programmable Logic Data Sheets for the most current value).

The frequency of the clock signal at the CLKIN input must be in a specific range depending on speed grade (see The Programmable Logic Data Sheets for the most current values). The CLKIN pin must be driven by an IBUFG or a BUFG.

On-chip synchronization is achieved by connecting the CLKFB input to a point on the global clock network driven by a BUFG, a global clock buffer. The BUFG input can only be connected to the CLK0 or CLK2X output of CLKDLLE. The BUFG connected to the CLKFB input of the CLKDLLE must be sourced from either the CLK0 or CLK2X outputs of the same CLKDLLE. The CLKIN input should be connected to the output of an IBUFG, with the IBUFG input connected to a pad driven by the system clock.

Off-chip synchronization is achieved by connecting the CLKFB input to the output of an IBUFG, with the IBUFG input connected to a pad. Either the CLK0 or CLK2X output can be used but not both. The CLK0 or CLK2X must be connected to the input of OBUF, an output buffer.

The duty cycle of the CLK0 output is 50-50 unless the DUTY\_CYCLE\_CORRECTION attribute is set to FALSE, in which case the duty cycle is the same as that of the CLKIN input. The duty cycle of the phase shifted outputs (CLK90, CLK180, and CLK270) is the same as that of the CLK0 output. The duty cycle of the CLK2X and CLKDV outputs is always 50-50. The frequency of the CLKDV output is determined by the value assigned to the CLKDV\_DIVIDE attribute.

The master reset input (RST) resets CLKDLL to its initial (power-on) state. The signal at the RST input is asynchronous and must be held High for just 2ns.

## Port Descriptions

Port	Function
CLK0	Clock at 1x CLKIN frequency
CLK180	Clock at 1x CLK0 frequency, shifted 180° with regards to CLK0
CLK270	Clock at 1x CLK0 frequency, shifted 270° with regards to CLK0
CLK2X	Clock at 2x CLK0 frequency, in phase with CLK0

Port	Function
CLK2X180	Clock at 1x CLK2X frequency shifted 180° with regards to CLK2X
CLK90	Clock at 1x CLK0 frequency, shifted 90° with regards to CLK0
CLKDV	Clock at (1/n) x CLK0 frequency, where n=CLKDV_DIVIDE value. CLKDV is in phase with CLK0.
LOCKED	CLKDLLE locked. CLKIN and CLKFB synchronized.

**Note** See the "PERIOD Specifications on CLKDLLs and DCM" in the Constraints Guide for additional information on using the TNM, TNM\_NET, and PERIOD attributes with CLKDLLE components.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- CLKDLLE: Delay Locked Loop Circuit for VirtexE and Spartan-IIE (Low frequency)
-- Xilinx HDL Libraries Guide, version 10.1.2

CLKDLLE_inst : CLKDLLE
generic map (
CLKDV_DIVIDE => 2.0, -- Divide by: 1.5,2.0,2.5,3.0,4.0,5.0,8.0 or 16.0
DUTY_CYCLE_CORRECTION => TRUE, -- Duty cycle correction, TRUE or FALSE
FACTORY_JF => X"C080", -- FACTORY JF Values
STARTUP_WAIT => FALSE) -- Delay config DONE until DLL LOCK, TRUE/FALSE
port map (

# CLKDLLHF

Primitive: High Frequency Clock Delay Locked Loop

## Introduction

This design element is a high frequency clock delay locked loop used to minimize clock skew. It synchronizes the clock signal at the feedback clock input (CLKFB) to the clock signal at the input clock (CLKIN). The locked output (LOCKED) is high when the two signals are in phase. The signals are considered to be in phase when their rising edges are within a specific range of each other (see The Programmable Logic Data Sheets for the most current value).

The frequency of the clock signal at the CLKIN input must be in a specific range depending on speed grade (see The Programmable Logic Data Sheets for the most current values). The CLKIN pin must be driven by an IBUFG or a BUFG.

On-chip synchronization is achieved by connecting the CLKFB input to a point on the global clock network driven by a BUFG, a global clock buffer. The BUFG input can only be connected to the CLK0 output of CLKDLLHF. The BUFG connected to the CLKFB input of the CLKDLLHF must be sourced from the CLK0 output of the same CLKDLLHF. The CLKIN input should be connected to the output of an IBUFG, with the IBUFG input connected to a pad driven by the system clock.

Off-chip synchronization is achieved by connecting the CLKFB input to the output of an IBUFG, with the IBUFG input connected to a pad. Only the CLK0 output can be used. CLK0 must be connected to the input of OBUF, an output buffer.

The duty cycle of the CLK0 output is 50-50 unless the DUTY\_CYCLE\_CORRECTION attribute is set to FALSE, in which case the duty cycle is the same as that of the CLKIN input. The duty cycle of the phase shifted output (CLK180) is the same as that of the CLK0 output. The frequency of the CLKDV output is determined by the value assigned to the CLKDV\_DIVIDE attribute.

The master reset input (RST) resets CLKDLL to its initial (power-on) state. The signal at the RST input is asynchronous and must be held High for just 2ns.

## Port Descriptions

Output	Function
CLK0	Clock at 1x CLKIN frequency
CLK180	Clock at 1x CLKIN frequency, shifted 180o with regards to CLK0
CLKDV	Clock at (1/n)x CLKIN frequency, n=CLKDV_DIVIDE value. CLKDV is in phase with CLK0.
LOCKED	CLKDLLHF locked

**Note** See the "PERIOD Specifications on CLKDLLs and DCM" section of the "Xilinx Constraints P" chapter in the Constraints Guide for additional information on using the TNM, TNM\_NET, and PERIOD attributes with CLKDLLHF components.

# DCM

Primitive: Digital Clock Manager

## Introduction

This design element is a digital clock manager that provides multiple functions. It can implement a clock delay locked loop, a digital frequency synthesizer, digital phase shifter, and a digital spread spectrum.

**Note** All unused inputs must be driven Low. The program will automatically tie the inputs Low if they are unused.

### *Clock Delay Locked Loop (DLL)*

DCM includes a clock delay locked loop used to minimize clock skew for Spartan-3, Virtex-II, Virtex-II Pro, and Virtex-II Pro X devices. DCM synchronizes the clock signal at the feedback clock input (CLKFB) to the clock signal at the input clock (CLKIN). The locked output (LOCKED) is high when the two signals are in phase. The signals are considered to be in phase when their rising edges are within a specified time (ps) of each other.

DCM supports two frequency modes for the DLL. By default, the DLL\_FREQUENCY\_MODE attribute is set to Low and the frequency of the clock signal at the CLKIN input must be in the Low (DLL\_CLKIN\_MIN\_LF to DLL\_CLKIN\_MAX\_LF) frequency range (MHz). In Low frequency mode, the CLK0, CLK90, CLK180, CLK270, CLK2X, CLKDV, and CLK2X180 outputs are available.

For up to and including Virtex-II Pro, you get only CLK0, CLK180, CLKDV, CLKFX and CLKFX180 in the HF mode. In Virtex-4, you get all outputs.

When the DLL\_FREQUENCY\_MODE attribute is set to High, the frequency of the clock signal at the CLKIN input must be in the High (DLL\_CLKIN\_MIN\_HF to DLL\_CLKIN\_MAX\_HF) frequency range (MHz). In High frequency mode, only the CLK0, CLK180, and CLKDV outputs are available.

On-chip synchronization is achieved by connecting the CLKFB input to a point on the global clock network driven by a BUFG, a global clock buffer. The BUFG connected to the CLKFB input of the DCM must be sourced from either the CLK0 or CLK2X outputs of the same DCM. The CLKIN input should be connected to the output of an IBUFG, with the IBUFG input connected to a pad driven by the system clock. Off-chip synchronization is achieved by connecting the CLKFB input to the output of an IBUFG, with the IBUFG input connected to a pad. Either the CLK0 or CLK2X output can be used but not both. The CLK0 or CLK2X must be connected to the input of OBUF, an output buffer. The CLK\_FEEDBACK attribute controls whether the CLK0 output, the default, or the CLK2X output is the source of the CLKFB input.

The duty cycle of the CLK0 output is 50-50 unless the DUTY\_CYCLE\_CORRECTION attribute is set to FALSE, in which case the duty cycle is the same as that of the CLKIN input. The duty cycle of the phase shifted outputs (CLK90, CLK180, and CLK270) is the same as that of the CLK0 output. The duty cycle of the CLK2X, CLK2X180, and CLKDV outputs is 50-50 unless CLKDV\_DIVIDE is a non-integer and the DLL\_FREQUENCY\_MODE is High (see CLKDV\_DIVIDE, in the Constraints Guide for details). The frequency of the CLKDV output is determined by the value assigned to the CLKDV\_DIVIDE attribute

#### DCM Clock Delay Lock Loop Outputs

Output	Description
CLK0	Clock at 1x CLKIN frequency
CLK180	Clock at 1x CLK0 frequency, shifted 180o with regards to CLK0
CLK270*	Clock at 1x CLK0 frequency, shifted 270o with regards to CLK0
CLK2X*	Clock at 2x CLK0 frequency, in phase with CLK0
CLK2X180*	Clock at 2x CLK0 frequency shifted 180o with regards to CLK2X
CLK90*	Clock at 1x CLK0 frequency, shifted 90o with regards to CLK0
CLKDV	Clock at (1/n) x CLK0 frequency, where n=CLKDV_DIVIDE value. CLKDV is in phase with CLK0.
LOCKED	All enabled DCM features locked.

\* The CLK90, CLK270, CLK2X, and CLK2X180 outputs are not available if the DLL\_FREQUENCY\_MODE is set to High.

#### Digital Frequency Synthesizer (DFS)

The CLKFX and CLKFX180 outputs in conjunction with the CLKFX\_MULTIPLY and CLKFX\_DIVIDE attributes provide a frequency synthesizer that can be any multiple or division of CLKIN. CLKFX and CLKIN are in phase every CLKFX\_MULTIPLY cycles of CLKFX and every CLKFX\_DIVIDE cycles of CLKIN when a feedback is provided to the CLKFB input of the DLL. The frequency of CLKFX is defined by the following equation.

$$\text{Frequency}_{\text{CLKFX}} = (\text{CLKFX\_MULTIPLY\_value} / \text{CLKFX\_DIVIDE\_value}) * \text{Frequency}_{\text{CLKIN}}$$

Both the CLKFX or CLKFX180 output can be used simultaneously. CLKFX180 is 1x the CLKFX frequency, shifted 180o with regards to CLKFX. CLKFX and CLKFX180 always have a 50/50 duty cycle. The DFS\_FREQUENCY\_MODE attribute specifies the allowable input clock and output clock frequency ranges. The CLK\_FEEDBACK attribute set to NONE will cause the DCM to be in the Digital Frequency Synthesizer mode. The CLKFX and CLKFX180 will be generated without phase correction with respect to CLKIN. The DSEN input pin for the DCM is no longer recommended for use and should remain unconnected in the design.

#### Digital Phase Shifter (DPS)

The phase shift (skew) between the rising edges of CLKIN and CLKFB may be configured as a fraction of the CLKIN period with the PHASE\_SHIFT attribute. This allows the phase shift to remain constant as ambient conditions change. The CLKOUT\_PHASE\_SHIFT attribute controls the use of the PHASE\_SHIFT value. By default, the CLKOUT\_PHASE\_SHIFT attribute is set to NONE and the PHASE\_SHIFT attribute has no effect.

By creating skew between CLKIN and CLKFB, all DCM output clocks are phase shifted by the amount of the skew. When the CLKOUT\_PHASE\_SHIFT attribute is set to FIXED, the skew set by the PHASE\_SHIFT attribute is used at configuration for the rising edges of CLKIN and CLKFB. The skew remains constant. When the CLKOUT\_PHASE\_SHIFT attribute is set to VARIABLE, the skew set at configuration is used as a starting point and the skew value can be changed dynamically during operation using the PS\* signals. This digital phase shifter feature is controlled by a synchronous interface. The inputs PSEN (phase shift enable) and PSINCDEC (phase shift increment/decrement) are set up to the rising edge of PSCLK (phase shift clock). The PSDONE (phase shift done) output is clocked with the rising edge of PSCLK (the phase shift clock). PSDONE must be connected to implement the complete synchronous interface. The rising-edge skew between CLKIN and CLKFB may be dynamically adjusted after the LOCKED output goes High. The PHASE\_SHIFT attribute value specifies the initial phase shift amount when the device is configured. Then the PHASE\_SHIFT value is changed one unit when PSEN is activated for one period of PSCLK. The PHASE\_SHIFT value is incremented when PSINCDEC is High and decremented when PSINCDEC is Low during the period that PSEN is High.

When the DCM completes an increment or decrement operation, the PSDONE output goes High for a single PSCLK cycle to indicate the operation is complete. At this point the next change may be made. When RST (reset) is High, the PHASE\_SHIFT attribute value is reset to the skew value set at configuration. If CLKOUT\_PHASE\_SHIFT is FIXED or NONE, the PSEN, PSINCDEC, and PSCLK inputs must be tied to GND. The program will automatically tie the inputs to GND if they are not connected by the user.

#### Additional Status Bits

The STATUS output bits return the following information:

Bit	Description
0	Phase Shift Overflow*
1 =  PHASE_SHIFT  > 255	
1	DLL CLKIN stopped**
1 = CLKIN stopped toggling	
2	DLL CLKFX stopped
1 = CLKFX stopped toggling	
3	No
4	No
5	No
6	No
7	No
* Phase Shift Overflow will also go high if the end of the phase shift delay line is reached (see the product data sheet for the most current value of the maximum shifting delay).	
** If only the DFS outputs are used (CLKFX & CLKFX180), this status bit will not go high if CLKIN stops.	

#### LOCKED

When LOCKED is high, all enabled signals are locked.

#### RST

The master reset input (RST) resets DCM to its initial (power-on) state. The signal at the RST input is asynchronous and must be held High for 2ns.

## Design Entry Method

Instantiation	Yes
Inference	No
Coregen and wizards	Recommended
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
SIM_MODE	String	"SAFE" or "FAST"	"SAFE"	This is a simulation only attribute. It will direct the simulation model to run in performance-oriented mode when set to "FAST." Please see the <i>Synthesis and Simulation Design Guide</i> for more information.

## FDCE

Primitive: D Flip-Flop with Clock Enable and Asynchronous Clear

## Introduction

This design element is a single D-type flip-flop with clock enable and asynchronous clear. When clock enable (CE) is High and asynchronous clear (CLR) is Low, the data on the data input (D) of this design element is transferred to the corresponding data output (Q) during the Low-to-High clock (C) transition. When CLR is High, it overrides all other inputs and resets the data output (Q) Low. When CE is Low, clock transitions are ignored.

For XC9500XL and XC9500XV devices, logic connected to the clock enable (CE) input may be implemented using the clock enable product term (p-term) in the macrocell, provided the logic can be completely implemented using the single p-term available for clock enable without requiring feedback from another macrocell. Only FDCE and FDPE flip-flops may take advantage of the clock-enable p-term.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs				Outputs

# FDCE\_1

Primitive: D Flip-Flop with Negative-Edge Clock, Clock Enable, and Asynchronous Clear

## Introduction

This design element is a single D-type flip-flop with data (D), clock enable (CE), asynchronous clear (CLR) inputs, and data output (Q). The asynchronous CLR input, when High, overrides all other inputs and sets the Q output Low. The data on the (D) input is loaded into the flip-flop when CLR is Low and CE is High on the High-to-Low clock (C) transition. When CE is Low, the clock transitions are ignored.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs				Outputs

# FDCPE

Primitive: D Flip-Flop with Clock Enable and Asynchronous Preset and Clear

## Introduction

This design element is a single D-type flip-flop with data (D), clock enable (CE), asynchronous preset (PRE), and asynchronous clear (CLR) inputs. The asynchronous active high PRE sets the Q output High; that active high CLR resets the output Low and has precedence over the PRE input. Data on the D input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the Low-to-High clock (C) transition. When CE is Low, the clock transitions are ignored and the previous value is retained. The FDCPE is generally implemented as a slice or IOB register within the device.

For FPGA devices, upon power-up, the initial value of this component is specified by the INIT attribute. If a subsequent GSR (Global Set/Reset) is asserted, the flop is asynchronously set to the INIT value.

**Note** While this device supports the use of asynchronous set and reset, it is not generally recommended to be used for in most cases. Use of asynchronous signals pose timing issues within the design that are difficult to detect and control and also have an adverse affect on logic optimization causing a larger design that can consume more power than if a synchronous set or reset is used.

## Logic Table

Inputs					Outputs
CLR	PRE	CE	D	C	Q

## FDCPE\_1

Primitive: D Flip-Flop with Negative-Edge Clock, Clock Enable, and Asynchronous Preset and Clear

## Introduction

FDCPE\_1 is a single D-type flip-flop with data (D), clock enable (CE), asynchronous preset (PRE), and asynchronous clear (CLR) inputs and data output (Q). The asynchronous PRE, when High, sets the (Q) output High; CLR, when High, resets the output Low. Data on the (D) input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the High-to-Low clock (C) transition. When CE is Low, the clock transitions are ignored.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs					Outputs
CLR	PRE	CE	D	C	Q
1	X	X	X	X	0
0	1	X	X	X	1
0	0	0	X	X	No Change
0	0	1	D	↓	D

## Port Descriptions

Port	Direction	Width	Function
Q	Output	1	Data output
C	Input	1	Clock input
CE	Input	1	Clock enable input
CLR	Input	1	Asynchronous clear input
D	Input	1	Data input
PRE	Input	1	Asynchronous set input

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary	0,1	0	Sets the initial value of Q output after configuration.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- FDCPE_1: Single Data Rate D Flip-Flop with Asynchronous Clear, Set and
--          Clock Enable (negedge clock). All families.
-- Xilinx HDL Libraries Guide, version 10.1.2

FDCPE_1_inst : FDCPE_1
generic map (
INIT => '0') -- Initial value of register ('0' or '1')
port map (
Q => Q,      -- Data output
C => C,      -- Clock input
CE => CE,    -- Clock enable input
CLR => CLR,  -- Asynchronous clear input
D => D,      -- Data input
PRE => PRE   -- Asynchronous set input
);

-- End of FDCPE_1_inst instantiation
    
```

## Verilog Instantiation Template

```

// FDCPE_1: Single Data Rate D Flip-Flop with Asynchronous Clear, Set and

# FDRSE

Primitive: D Flip-Flop with Synchronous Reset and Set and Clock Enable

## Introduction

FDRSE is a single D-type flip-flop with synchronous reset (R), synchronous set (S), clock enable (CE) inputs. The reset (R) input, when High, overrides all other inputs and resets the Q output Low during the Low-to-High clock transition. (Reset has precedence over Set.) When the set (S) input is High and R is Low, the flip-flop is set, output High, during the Low-to-High clock (C) transition. Data on the D input is loaded into the flip-flop when R and S are Low and CE is High during the Low-to-High clock transition.

Upon power-up, the initial value of this component is specified by the INIT attribute. If a subsequent GSR (Global Set/Reset) is asserted, the flop is asynchronously set to the INIT value.

## Logic Table

Inputs					Outputs
R	S	CE	D	C	Q
1	X	X	X	↑	0
0	1	X	X	↑	1
0	0	0	X	X	No Change
0	0	1	1	↑	1
0	0	1	0	↑	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary	0 or 1	0	Sets the initial value of Q output after configuration and on GSR.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- FDRSE: Single Data Rate D Flip-Flop with Synchronous Clear, Set and
--       Clock Enable (posedge clk). All families.
-- Xilinx HDL Libraries Guide, version 10.1.2

FDRSE_inst : FDRSE
generic map (
  INIT => '0') -- Initial value of register ('0' or '1')
port map (
  Q => Q,      -- Data output
  C => C,      -- Clock input
  CE => CE,    -- Clock enable input
  D => D,      -- Data input
  R => R,      -- Synchronous reset input
  S => S       -- Synchronous set input
);

-- End of FDRSE_inst instantiation
```

# IBUF

Primitive: Input Buffer

## Introduction

This design element is automatically inserted (inferred) by the synthesis tool to any signal directly connected to a top-level input or in-out port of the design. You should generally let the synthesis tool infer this buffer. However, it can be instantiated into the design if required. In order to do so, connect the input port (I) directly to the associated top-level input or in-out port, and connect the output port (O) to the logic sourced by that port. Modify any necessary generic maps (VHDL) or named parameter value assignment (Verilog) in order to change the default behavior of the component.

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Buffer input
I	Input	1	Buffer output

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

In general, this element is inferred by the synthesis tool for any specified top-level input port to the design. It is generally not necessary to specify them in the source code however if desired, they be manually instantiated by either copying the instantiation code from the ISE Libraries Guide HDL Template and paste it into the top-level entity/module of your code. It is recommended to always put all I/O components on the top-level of the design to help facilitate hierarchical design methods. Connect the I port directly to the top-level input port of the design and the O port to the logic in which this input is to source. Specify the desired generic/defparam values in order to configure the proper behavior of the buffer.

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- IBUF: Single-ended Input Buffer
--     All devices
-- Xilinx HDL Libraries Guide, version 10.1.2

IBUF_inst : IBUF
generic map (
IBUF_DELAY_VALUE => "0", -- Specify the amount of added input delay for buffer, "0"-16" (Spartan-3E/3A only)
IFD_DELAY_VALUE => "AUTO", -- Specify the amount of added delay for input register, "AUTO", "0"-8" (Spartan-3E/3A only)
IOSTANDARD => "DEFAULT")
port map (
O => O,      -- Buffer output
I => I       -- Buffer input (connect directly to top-level port)
);

-- End of IBUF_inst instantiation
```

## Verilog Instantiation Template

```
// IBUF: Single-ended Input Buffer
//     All devices
// Xilinx HDL Libraries Guide, version 10.1.2

IBUF #(
.IBUF_DELAY_VALUE("0"), // Specify the amount of added input delay for
// the buffer, "0"-16" (Spartan-3E/3A only)
.IFD_DELAY_VALUE("AUTO"), // Specify the amount of added delay for input
// register, "AUTO", "0"-8" (Spartan-3E/3A only)
.IOSTANDARD("DEFAULT") // Specify the input I/O standard
)IBUF_inst (
.O(O), // Buffer output
.I(I) // Buffer input (connect directly to top-level port)
);

// End of IBUF_inst instantiation
```

# IBUFDS

Primitive: Differential Signaling Input Buffer with Optional Delay

## Introduction

This design element is an input buffer that supports low-voltage, differential signaling. In IBUFDS, a design level interface signal is represented as two distinct ports (I and IB), one deemed the "master" and the other the "slave." The master and the slave are opposite phases of the same logical signal (for example, MYNET\_P and MYNET\_N). Optionally, a programmable differential termination feature is available to help improve signal integrity and reduce external components. Also available is a programmable delay to assist in the capturing of incoming data to the device.

## Logic Table

Inputs		Outputs
I	IB	O
0	0	No Change
0	1	0
1	0	1
1	1	No Change

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Diff_p Buffer Input
IB	Input	1	Diff_n Buffer Input
I	Input	1	Buffer Output

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

Put all I/O components on the top-level of the design to help facilitate hierarchical design methods. Connect the I port directly to the top-level "master" input port of the design, the IB port to the top-level "slave" input port, and the O port to the logic in which this input is to source. Specify the desired generic/defparam values in order to configure the proper behavior of the buffer.

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- IBUFDS: Differential Input Buffer
--       Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

IBUFDS_inst : IBUFDS
generic map (
CAPACITANCE => "DONT_CARE", -- "LOW", "NORMAL", "DONT_CARE" (Virtex-4 only)
DIFF_TERM => FALSE, -- Differential Termination (Virtex-4/5, Spartan-3E/3A)
IBUF_DELAY_VALUE => "0", -- Specify the amount of added input delay for buffer, "0"-16" (Spartan-3E/3A only)
IFD_DELAY_VALUE => "AUTO", -- Specify the amount of added delay for input register, "AUTO", "0"-8" (Spartan-3E/3A only)
IOSTANDARD => "DEFAULT")
port map (
O => O, -- Clock buffer output
I => I, -- Diff_p clock buffer input (connect directly to top-level port)
IB => IB -- Diff_n clock buffer input (connect directly to top-level port)
);

-- End of IBUFDS_inst instantiation
    
```

## Verilog Instantiation Template

```

// IBUFDS: Differential Input Buffer
//       Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

IBUFDS #(
.CAPACITANCE("DONT_CARE"), // "LOW", "NORMAL", "DONT_CARE" (Virtex-4 only)
.DIFF_TERM("FALSE"), // Differential Termination (Virtex-4/5, Spartan-3E/3A)
.IBUF_DELAY_VALUE("0"), // Specify the amount of added input delay for
// the buffer, "0"-16" (Spartan-3E only)
.IFD_DELAY_VALUE("AUTO"), // Specify the amount of added delay for input
// register, "AUTO", "0"-8" (Spartan-3E/3A only)
.IOSTANDARD("DEFAULT") // Specify the input I/O standard
) IBUFDS_inst (
.O(O), // Buffer output
.I(I), // Diff_p buffer input (connect directly to top-level port)
.IB(IB) // Diff_n buffer input (connect directly to top-level port)
);

// End of IBUFDS_inst instantiation
    
```

## IBUFG

Primitive: Dedicated Input Clock Buffer

## Introduction

The IBUFG is a dedicated input to the device which should be used to connect incoming clocks to the FPGA to the global clock routing resources. The IBUFG provides dedicated connections to the DCM\_SP and BUFG providing the minimum amount of clock delay and jitter to the device. The IBUFG input can only be driven by the global clock pins. The IBUFG output can drive CLKIN of a DCM\_SP, BUFG, or your choice of logic. The IBUFG can be routed to your choice of logic to allow the use of the dedicated clock pins for general logic.

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Clock Buffer input
I	Input	1	Clock Buffer output

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- IBUFG: Global Clock Buffer (sourced by an external pin)
-- Xilinx HDL Libraries Guide, version 10.1.2

IBUFG_inst : IBUFG
generic map (
  IOSTANDARD => "DEFAULT")
port map (
  O => O, -- Clock buffer output
  I => I -- Clock buffer input (connect directly to top-level port)
```

### Libraries Guide

```
);  
-- End of IBUFG_inst instantiation
```

## Verilog Instantiation Template

```
// IBUFG: Global Clock Buffer (sourced by an external pin)  
// All FPGAs  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
IBUFG #(  
  .IOSTANDARD("DEFAULT")  
) IBUFG_inst (  
  .O(O), // Clock buffer output  
  .I(I) // Clock buffer input (connect directly to top-level port)  
);  
  
// End of IBUFG_inst instantiation
```

## IBUFGDS

Primitive: Differential Signaling Dedicated Input Clock Buffer and Optional Delay

## Introduction

This design element is a dedicated differential signaling input buffer for connection to the clock buffer (BUFG) or DCM. In IBUFGDS, a design-level interface signal is represented as two distinct ports (I and IB), one deemed the "master" and the other the "slave." The master and the slave are opposite phases of the same logical signal (for example, MYNET\_P and MYNET\_N). Optionally, a programmable differential termination feature is available to help improve signal integrity and reduce external components. Also available is a programmable delay is to assist in the capturing of incoming data to the device.

## Logic Table

Inputs		Outputs
I	IB	O
0	0	No Change
0	1	0
1	0	1
1	1	No Change

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Diff_p Clock Buffer Input
IB	Input	1	Diff_n Clock Buffer Input
I	Input	1	Clock Buffer output

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

Put all I/O components on the top-level of the design to help facilitate hierarchical design methods. Connect the I port directly to the top-level "master" input port of the design, the IB port to the top-level "slave" input port and the O port to a DCM, BUFG or logic in which this input is to source. Some synthesis tools infer the BUFG automatically if necessary, when connecting an IBUFG to the clock resources of the FPGA. Specify the desired generic/defparam values in order to configure the proper behavior of the buffer.

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

# IFDDRCPE

Primitive: Dual Data Rate Input D Flip-Flop with Clock Enable and Asynchronous Preset and Clear

## Introduction

This design element is a dual data rate (DDR) input D flip-flop with clock enable (CE) and asynchronous preset (PRE) and clear (CLR). It consists of one input buffer and two identical flip-flops (FDCPE).

When the asynchronous PRE is High and CLR is Low, both the Q0 and Q1 outputs are set High. When CLR is High, both outputs are reset Low. When PRE and CLR are Low and CE is High, data on the D input is loaded into the Q0 output on the Low-to-High C0 clock transition, and into the Q1 output on the Low-to-High C1 clock transition.

The INIT attribute does not apply to this design elements components.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs						Outputs	
C0	C1	CE	D	CLR	PRE	Q0	Q1
X	X	X	X	1	0	0	0
X	X	X	X	0	1	1	1
X	X	X	X	1	1	0	0
X	X	0	X	0	0	No Change	No Change
↑	X	1	D	0	0	D	No Change
X	↑	1	D	0	0	No Change	D

## Design Entry Method

Instantiation	Yes
Inference	Recommended

# IFDDRSE

Primitive: Dual Data Rate Input D Flip-Flop with Synchronous Reset and Set and Clock Enable

## Introduction

This design element is a dual data rate (DDR) input D flip-flop with synchronous reset (R), synchronous set (S), and clock enable (CE). It consists of one input buffer and two identical flip-flops (FDRSE).

For the C0 input and Q0 output, reset (R) has precedence. The R input, when High, resets the Q0 output Low during the Low-to-High C0 clock transition. When S is High and R is Low, the Q0 output is set High during the Low-to-High C0 clock transition. For the C1 input and Q1 output, set (S) has precedence. The R input, when High, resets the Q1 output Low during the Low-to-High C1 clock transition. When S is High and R is Low, the Q0 output is set to High during the Low-to-High C1 clock transition.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

The INIT attribute does not apply to this element.

## Logic Table

Inputs						Outputs	
C0	C1	CE	D	R	S	Q0	Q1
↑	X	X	X	1	0	0	No Change
↑	X	X	X	0	1	1	No Change
↑	X	X	X	1	1	0	No Change
X	↑	X	X	1	0	No Change	0
X	↑	X	X	0	1	No Change	1
X	↑	X	X	1	1	No Change	0
X	X	0	X	0	0	No Change	No Change
↑	X	1	D	0	0	D	No Change
X	↑	1	D	0	0	No Change	D

# IOBUF

Primitive: Bi-Directional Buffer

## Introduction

The design element is a bidirectional single-ended I/O Buffer used to connect internal logic to an external bidirectional pin.

## Logic Table

Inputs		Bidirectional	Outputs
T	I	IO	O
1	X	Z	X
0	1	1	1
0	0	0	0

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Buffer output
IO	Inout	1	Buffer inout
I	Input	1	Buffer input
T	Input	1	3-State enable input

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
DRIVE	Integer	2, 4, 6, 8, 12, 16, 24	12	Selects output drive strength (mA) for the SelectIO buffers that use the LVTTTL, LVCMOS12, LVCMOS15, LVCMOS18, LVCMOS25, or LVCMOS33 interface I/O standard.
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.
SLEW	String	"SLOW", "FAST"	"SLOW"	Sets the output rise and fall time. See the Data Sheet for recommendations of the best setting for this attribute.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- IOBUF: Single-ended Bi-directional Buffer
--     All devices
-- Xilinx HDL Libraries Guide, version 10.1.2

IOBUF_inst : IOBUF
generic map (
DRIVE => 12,
IBUF_DELAY_VALUE => "0", -- Specify the amount of added input delay for buffer, "0"-16" (Spartan-3E/3A only)
IFD_DELAY_VALUE => "AUTO", -- Specify the amount of added delay for input register, "AUTO", "0"-8" (Spartan-3E/3A only)
IOSTANDARD => "DEFAULT",
SLEW => "SLOW")
port map (
O => O,      -- Buffer output
IO => IO,    -- Buffer inout port (connect directly to top-level port)
I => I,      -- Buffer input
T => T      -- 3-state enable input
);

-- End of IOBUF_inst instantiation

```

## Verilog Instantiation Template

```

// IOBUF: Single-ended Bi-directional Buffer
//     All devices
// Xilinx HDL Libraries Guide, version 10.1.2

IOBUF #(
.DRIVE(12), // Specify the output drive strength
.IBUF_DELAY_VALUE("0"), // Specify the amount of added input delay for the buffer, "0"-16" (Spartan-3E only)
.IFD_DELAY_VALUE("AUTO"), // Specify the amount of added delay for input register, "AUTO", "0"-8" (Spartan-3E only)
.IOSTANDARD("DEFAULT"), // Specify the I/O standard
.SLEW("SLOW") // Specify the output slew rate
) IOBUF_inst (

# IOBUFDS

Primitive: 3-State Differential Signaling I/O Buffer with Active Low Output Enable

## Introduction

The design element is a bidirectional buffer that supports low-voltage, differential signaling. For the IOBUFDS, a design level interface signal is represented as two distinct ports (IO and IOB), one deemed the "master" and the other the "slave." The master and the slave are opposite phases of the same logical signal (for example, MYNET\_P and MYNET\_N). Optionally, a programmable differential termination feature is available to help improve signal integrity and reduce external components. Also available is a programmable delay to assist in the capturing of incoming data to the device.

## Logic Table

Inputs		Bidirectional		Outputs
I	T	IO	IOB	O
X	1	Z	Z	No Change
0	0	0	1	0
1	0	1	0	1

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Buffer output
IO	Inout	1	Diff_p inout
IOB	Inout	1	Diff_n inout
I	Input	1	Buffer input
T	Input	1	3-state enable input

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- IOBUFDS: Differential Bi-directional Buffer
--       Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

IOBUFDS_inst : IOBUFDS
generic map (
IBUF_DELAY_VALUE => "0", -- Specify the amount of added input delay for buffer, "0"-16" (Spartan-3E/3A only)
IFD_DELAY_VALUE => "AUTO", -- Specify the amount of added delay for input register, "AUTO", "0"-8" (Spartan-3E/3A only)
IOSTANDARD => "DEFAULT")
port map (
O => O,      -- Buffer output
IO => IO,    -- Diff_p inout (connect directly to top-level port)
IOB => IOB,  -- Diff_n inout (connect directly to top-level port)
I => I,      -- Buffer input
T => T      -- 3-state enable input
);

-- End of IOBUFDS_inst instantiation
    
```

## Verilog Instantiation Template

```

// IOBUFDS: Differential Bi-directional Buffer

# KEEPER

Primitive: KEEPER Symbol

## Introduction

The design element is a weak keeper element that retains the value of the net connected to its bidirectional O pin. For example, if a logic 1 is being driven onto the net, KEEPER drives a weak/resistive 1 onto the net. If the net driver is then 3-stated, KEEPER continues to drive a weak/resistive 1 onto the net.

## Port Descriptions

Name	Direction	Width	Function
O	Output	1-Bit	Keeper output

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;
```

```
-- KEEPER: I/O Buffer Weak Keeper
--           All FPGA, CoolRunner-II
-- Xilinx HDL Libraries Guide, version 10.1.2

KEEPER_inst : KEEPER
port map (
O => O      -- Keeper output (connect directly to top-level port)
);

-- End of KEEPER_inst instantiation
```

## Verilog Instantiation Template

```
// KEEPER: I/O Buffer Weak Keeper
//           All FPGA, CoolRunner-II
// Xilinx HDL Libraries Guide, version 10.1.2

KEEPER KEEPER_inst (
.O(O)      // Keeper output (connect directly to top-level port)
);

// End of KEEPER_inst instantiation
```

# LDCPE

Primitive: Transparent Data Latch with Asynchronous Clear and Preset and Gate Enable

## Introduction

This design element is a transparent data latch with data (D), asynchronous clear (CLR), asynchronous preset (PRE), and gate enable (GE). When (CLR) is High, it overrides the other inputs and resets the data (Q) output Low. When (PRE) is High and (CLR) is Low, it presets the data (Q) output High. Q reflects the data (D) input while the gate (G) input and gate enable (GE) are High and (CLR) and PRE are Low. The data on the (D) input during the High-to-Low gate transition is stored in the latch. The data on the Q output remains unchanged as long as (G) or (GE) remains Low.

This latch is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs					Outputs
CLR	PRE	GE	G	D	Q
1	X	X	X	X	0
0	1	X	X	X	1
0	0	0	X	X	No Change
0	0	1	1	0	0
0	0	1	1	1	1
0	0	1	0	X	No Change
0	0	1	↓	D	D

## Port Descriptions

Port	Direction	Width	Function
Q	Output	1	Data Output
CLR	Input	1	Asynchronous clear/reset input
D	Input	1	Data Input
G	Input	1	Gate Input
GE	Input	1	Gate Enable Input
PRE	Input	1	Asynchronous preset/set input

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Integer	0 or 1	0	Sets the initial value of Q output after configuration.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- LDCPE: Transparent latch with Asynchronous Reset, Preset and
--       Gate Enable.
--       All families.
-- Xilinx HDL Libraries Guide, version 10.1.2

LDCPE_inst : LDCPE
generic map (
INIT => '0') -- Initial value of latch ('0' or '1')
port map (
Q => Q,      -- Data output
CLR => CLR,  -- Asynchronous clear/reset input
D => D,      -- Data input
G => G,      -- Gate input
GE => GE,   -- Gate enable input
PRE => PRE  -- Asynchronous preset/set input
);

-- End of LDCPE_inst instantiation
```

## Verilog Instantiation Template

```
// LDCPE: Transparent latch with Asynchronous Reset, Preset and
//       Gate Enable.
//       All families.
// Xilinx HDL Libraries Guide, version 10.1.2

# LUT1

Primitive: 1-Bit Look-Up-Table with General Output

## Introduction

This design element is a 1-bit look-up-tables (LUT) with general output (O).

An INIT attribute with an appropriate number of hexadecimal digits for the number of inputs must be attached to the LUT to specify its function. This element provides a look-up-table version of a buffer or inverter. These elements are the basic building blocks. Two LUTs are available in each CLB slice; four LUTs are available in each CLB. Multiple variants of LUTs accommodate additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

The INIT parameter for the FPGA LUT primitive is what gives the LUT its logical value. By default, this value is zero, thus driving the output to a zero regardless of the input values (acting as a ground). However, in most cases a new INIT value must be determined in order to specify the logic function for the LUT primitive. There are at least two methods by which the LUT value can be determined:

**The Truth Table Method** -A common method to determine the desired INIT value for a LUT is using a truth table. To do so, simply create a binary truth table of all possible inputs, specify the desired logic value of the output and then create the INIT string from those output values.

**The Equation Method** -Another method to determine the LUT value is to define parameters for each input to the LUT that correspond to their listed truth value and use those to build the logic equation you are after. This method is easier to understand once you have grasped the concept and more self-documenting than the above method however does require the code to first specify the appropriate parameters.

## Logic Table

Inputs	Outputs
I0	O
0	INIT[0]
1	INIT[1]
INIT = Binary number assigned to the INIT attribute	

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 2-Bit Value	All zeros	Initializes look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# LUT1\_D

Primitive: 1-Bit Look-Up-Table with Dual Output

## Introduction

This design element is a 1-bit look-up-table (LUT) with two functionally identical outputs, O and LO. It provides a look-up-table version of a buffer or inverter.

The O output is a general interconnect. The LO output is used to connect to another output within the same CLB slice and to the fast connect buffer. A mandatory INIT attribute, with an appropriate number of hexadecimal digits for the number of inputs, must be attached to the LUT to specify its function.

The INIT parameter for the FPGA LUT primitive is what gives the LUT its logical value. By default, this value is zero, thus driving the output to a zero regardless of the input values (acting as a ground). However, in most cases a new INIT value must be determined in order to specify the logic function for the LUT primitive. There are at least two methods by which the LUT value can be determined:

**The Truth Table Method** -A common method to determine the desired INIT value for a LUT is using a truth table. To do so, simply create a binary truth table of all possible inputs, specify the desired logic value of the output and then create the INIT string from those output values.

**The Equation Method** -Another method to determine the LUT value is to define parameters for each input to the LUT that correspond to their listed truth value and use those to build the logic equation you are after. This method is easier to understand once you have grasped the concept and more self-documenting than the above method however does require the code to first specify the appropriate parameters.

## Logic Table

# LUT2\_D

Primitive: 2-Bit Look-Up-Table with Dual Output

## Introduction

This design element is a 2-bit look-up-tables (LUTs) with two functionally identical outputs, O and LO.

The O output is a general interconnect. The LO output is used to connect to another output within the same CLB slice and to the fast connect buffer. A mandatory INIT attribute, with an appropriate number of hexadecimal digits for the number of inputs, must be attached to the LUT to specify its function.

The INIT parameter for the FPGA LUT primitive is what gives the LUT its logical value. By default, this value is zero, thus driving the output to a zero regardless of the input values (acting as a ground). However, in most cases a new INIT value must be determined in order to specify the logic function for the LUT primitive. There are at least two methods by which the LUT value can be determined:

**The Truth Table Method** -A common method to determine the desired INIT value for a LUT is using a truth table. To do so, simply create a binary truth table of all possible inputs, specify the desired logic value of the output and then create the INIT string from those output values.

**The Equation Method** -Another method to determine the LUT value is to define parameters for each input to the LUT that correspond to their listed truth value and use those to build the logic equation you are after. This method is easier to understand once you have grasped the concept and more self-documenting than the above method however does require the code to first specify the appropriate parameters.

## Logic Table

Inputs		Outputs	
I1	I0	O	LO
0	0	INIT[0]	INIT[0]
0	1	INIT[1]	INIT[1]
1	0	INIT[2]	INIT[2]
1	1	INIT[3]	INIT[3]

INIT = Binary equivalent of the hexadecimal number assigned to the INIT attribute

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 4-Bit Value	All zeros	Initializes look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

# LUT3

Primitive: 3-Bit Look-Up-Table with General Output

## Introduction

This design element is a 3-bit look-up-table (LUT) with general output (O). A mandatory INIT attribute, with an appropriate number of hexadecimal digits for the number of inputs, must be attached to the LUT to specify its function.

An INIT attribute with an appropriate number of hexadecimal digits for the number of inputs must be attached to the LUT to specify its function. This element provides a look-up-table version of a buffer or inverter. These elements are the basic building blocks. Two LUTs are available in each CLB slice; four LUTs are available in each CLB. Multiple variants of LUTs accommodate additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

## Logic Table

Inputs			Outputs
I2	I1	I0	O
0	0	0	INIT[0]
0	0	1	INIT[1]
0	1	0	INIT[2]
0	1	1	INIT[3]
1	0	0	INIT[4]
1	0	1	INIT[5]
1	1	0	INIT[6]
1	1	1	INIT[7]

INIT = Binary equivalent of the hexadecimal number assigned to the INIT attribute

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 8-Bit Value	All zeros	Initializes look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# MULT\_AND

Primitive: Fast Multiplier AND

## Introduction

The design element is an AND component located within the slice where the two inputs are shared with the 4-input LUT and the output drives into the carry logic. This added logic is especially useful for building fast and smaller multipliers however be used for other purposes as well. The I1 and I0 inputs must be connected to the I1 and I0 inputs of the associated LUT. The LO output must be connected to the DI input of the associated MUXCY, MUXCY\_D, or MUXCY\_L.

## Logic Table

Inputs		Outputs
I1	I0	LO
0	0	0
0	1	0
1	0	0
1	1	1

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MULT_AND: 2-input AND gate connected to Carry chain
--           All FPGA devices except Virtex-5
-- Xilinx HDL Libraries Guide, version 10.1.2

MULT_AND_inst : MULT_AND
port map (
LO => LO,    -- MULT_AND output (connect to MUXCY DI)
I0 => I0,    -- MULT_AND data[0] input
I1 => I1     -- MULT_AND data[1] input
);

-- End of MULT_AND_inst instantiation
```

## Verilog Instantiation Template

```
// MULT_AND: 2-input AND gate connected to Carry chain
//           For use with all FPGAs except Virtex-5
// Xilinx HDL Libraries Guide, version 10.1.2

MULT_AND MULT_AND_inst (
  .LO(IO),    // MULT_AND output (connect to MUXCY DI)
  .I0(I0),   // MULT_AND data[0] input
  .I1(I1)    // MULT_AND data[1] input
);

// End of MULT_AND_inst instantiation
```

## For More Information

- See the [Virtex-II Data Sheets](#).

# MULT18X18

Primitive: 18 x 18 Signed Multiplier

## Introduction

MULT18X18 is a combinational signed 18-bit by 18-bit multiplier. The value represented in the 18-bit input A is multiplied by the value represented in the 18-bit input B. Output P is the 36-bit product of A and B.

## Logic Table

Inputs		Output
A	B	P
A	B	$A \times B$
A, B, and P are two's complement.		

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MULT18X18: 18 x 18 signed asynchronous multiplier
--           Virtex-II/II-Pro, Spartan-3
-- Xilinx HDL Libraries Guide, version 10.1.2

MULT18X18_inst : MULT18X18
port map (
P => P,      -- 36-bit multiplier output
A => A,      -- 18-bit multiplier input
B => B       -- 18-bit multiplier input
);

-- End of MULT18X18_inst instantiation
```

## Verilog Instantiation Template

```
// MULT18X18: 18 x 18 signed asynchronous multiplier
```

```
//          Virtex-II/II-Pro, Spartan-3
// Xilinx HDL Libraries Guide, version 10.1.2

MULT18X18 MULT18X18_inst (
.P(P),      // 36-bit multiplier output
.A(A),      // 18-bit multiplier input
.B(B)       // 18-bit multiplier input
);

// End of MULT18X18_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# MULT18X18S

Primitive: 18 x 18 Signed Multiplier – Registered Version

## Introduction

MULT18X18S is the registered version of the 18 x 18 signed multiplier with output P and inputs A, B, C, CE, and R. The registers are initialized to 0 after the GSR pulse.

The value represented in the 18-bit input A is multiplied by the value represented in the 18-bit input B. Output P is the 36-bit product of A and B.

## Logic Table

Inputs					Output
C	CE	Am	Bn	R	P
↑	X	X	X	1	0
↑	1	Am	Bn	0	A x B
X	0	X	X	0	No Change

A, B, and P are two's complement.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MULT18X18S: 18 x 18 signed synchronous multiplier
--           Virtex-II/II-Pro, Spartan-3
-- Xilinx HDL Libraries Guide, version 10.1.2

MULT18X18S_inst : MULT18X18S
port map (

```

```
P => P,    -- 36-bit multiplier output
A => A,    -- 18-bit multiplier input
B => B,    -- 18-bit multiplier input
C => C,    -- Clock input
CE => CE,  -- Clock enable input
R => R     -- Synchronous reset input
);

-- End of MULT18X18S_inst instantiation
```

## Verilog Instantiation Template

```
// MULT18X18S: 18 x 18 signed synchronous multiplier
//           Virtex-II/II-Pro, Spartan-3
// Xilinx HDL Libraries Guide, version 10.1.2

MULT18X18S MULT18X18S_inst (
.P(P),    // 36-bit multiplier output
.A(A),    // 18-bit multiplier input
.B(B),    // 18-bit multiplier input
.C(C),    // Clock input
.CE(CE),  // Clock enable input
.R(R)     // Synchronous reset input
);

// End of MULT18X18S_inst instantiation
```

# MUXCY

Primitive: 2-to-1 Multiplexer for Carry Logic with General Output

## Introduction

The direct input (DI) of a slice is connected to the (DI) input of the MUXCY. The carry in (CI) input of an LC is connected to the CI input of the MUXCY. The select input (S) of the MUXCY is driven by the output of the Look-Up Table (LUT) and configured as a MUX function. The carry out (O) of the MUXCY reflects the state of the selected input and implements the carry out function of each LC. When Low, S selects DI; when High, S selects CI.

The variants “MUXCY\_D” and “MUXCY\_L” provide additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

## Logic Table

Inputs			Outputs
S	DI	CI	O
0	1	X	1
0	0	X	0
1	X	1	1
1	X	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXCY: Carry-Chain MUX with general output
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXCY_inst : MUXCY
port map (
O => O, -- Carry output signal
CI => CI, -- Carry input signal
DI => DI, -- Data input signal
S => S -- MUX select, tie to '1' or LUT4 out

```

```
);  
-- End of MUXCY_inst instantiation
```

## Verilog Instantiation Template

```
// MUXCY: Carry-Chain MUX with general output  
// For use with All FPGAs  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
MUXCY MUXCY_inst (  
  .O(O), // Carry output signal  
  .CI(CI), // Carry input signal  
  .DI(DI), // Data input signal  
  .S(S) // MUX select, tie to '1' or LUT4 out  
);  
  
// End of MUXCY_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# MUXCY\_D

Primitive: 2-to-1 Multiplexer for Carry Logic with Dual Output

## Introduction

This design element implements a 1-bit, high-speed carry propagate function. One such function can be implemented per logic cell (LC), for a total of 4-bits per configurable logic block (CLB). The direct input (DI) of an LC is connected to the DI input of the MUXCY\_D. The carry in (CI) input of an LC is connected to the CI input of the MUXCY\_D. The select input (S) of the MUX is driven by the output of the Look-Up Table (LUT) and configured as an XOR function. The carry out (O and LO) of the MUXCY\_D reflects the state of the selected input and implements the carry out function of each LC. When Low, S selects DI; when High, S selects CI.

Outputs O and LO are functionally identical. The O output is a general interconnect. See also “MUXCY” and “MUXCY\_L”.

## Logic Table

Inputs			Outputs	
S	DI	CI	O	LO
0	1	X	1	1
0	0	X	0	0
1	X	1	1	1
1	X	0	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXCY_D: Carry-Chain MUX with general and local outputs
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXCY_D_inst : MUXCY_D
port map (
    LO => LO, -- Carry local output signal
    
```

```
O => O,    -- Carry general output signal
CI => CI,  -- Carry input signal
DI => DI,  -- Data input signal
S => S     -- MUX select, tie to '1' or LUT4 out
);

-- End of MUXCY_D_inst instantiation
```

## Verilog Instantiation Template

```
// MUXCY_D: Carry-Chain MUX with general and local outputs
//           For use with All FPGAs
// Xilinx HDL Libraries Guide, version 10.1.2

MUXCY_D MUXCY_D_inst (
    .LO(LO), // Carry local output signal
    .O(O),   // Carry general output signal
    .CI(CI), // Carry input signal
    .DI(DI), // Data input signal
    .S(S)    // MUX select, tie to '1' or LUT4 out
);

// End of MUXCY_D_inst instantiation
```

## For More Information

# MUXCY\_L

Primitive: 2-to-1 Multiplexer for Carry Logic with Local Output

## Introduction

This design element implements a 1-bit high-speed carry propagate function. One such function is implemented per logic cell (LC), for a total of 4-bits per configurable logic block (CLB). The direct input (DI) of an LC is connected to the DI input of the MUXCY\_L. The carry in (CI) input of an LC is connected to the CI input of the MUXCY\_L. The select input (S) of the MUXCY\_L is driven by the output of the Look-Up Table (LUT) and configured as an XOR function. The carry out (LO) of the MUXCY\_L reflects the state of the selected input and implements the carry out function of each (LC). When Low, (S) selects DI; when High, (S) selects (CI).

See also “MUXCY” and “MUXCY\_D.”

## Logic Table

Inputs			Outputs
S	DI	CI	LO
0	1	X	1
0	0	X	0
1	X	1	1
1	X	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXCY_L: Carry-Chain MUX with local output
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXCY_L_inst : MUXCY_L
port map (
LO => LO, -- Carry local output signal
CI => CI, -- Carry input signal
DI => DI, -- Data input signal

```

```
S => S    -- MUX select, tie to '1' or LUT4 out
);

-- End of MUXCY_L_inst instantiation
```

## Verilog Instantiation Template

```
// MUXCY_L: Carry-Chain MUX with local output
//           For use with All FPGAs
// Xilinx HDL Libraries Guide, version 10.1.2

MUXCY_L MUXCY_L_inst (
  .LO(LO), // Carry local output signal
  .CI(CI), // Carry input signal
  .DI(DI), // Data input signal
  .S(S)    // MUX select, tie to '1' or LUT4 out
);

// End of MUXCY_L_inst instantiation
```

# MUXF5

Primitive: 2-to-1 Look-Up Table Multiplexer with General Output

## Introduction

This design element provides a multiplexer function in a CLB slice for creating a function-of-5 lookup table or a 4-to-1 multiplexer in combination with the associated lookup tables. The local outputs (LO) from the two lookup tables are connected to the I0 and I1 inputs of the MUXF5. The (S) input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

The variants, "MUXF5\_D" and "MUXF5\_L", provide additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

## Logic Table

Inputs			Outputs
S	I0	I1	O
0	1	X	1
0	0	X	0
1	X	1	1
1	X	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF5: Slice MUX to tie two LUT4's together with general output
-- All FPGA Devices except Virtex-5
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF5_inst : MUXF5
port map (
O => O, -- Output of MUX to general routing
I0 => I0, -- Input (tie directly to the output of LUT4)
I1 => I1, -- Input (tie directly to the output of LUT4)
S => S -- Input select to MUX
    
```

```
);  
-- End of MUXF5_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF5: Slice MUX to tie two LUT4's together with general output  
// For use with All FPGAs except Virtex-5  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
MUXF5 MUXF5_inst (  
  .O(O), // Output of MUX to general routing  
  .I0(I0), // Input (tie directly to the output of LUT4)  
  .I1(I1), // Input (tie directly to the output of LUT4)  
  .S(S) // Input select to MUX  
);  
  
// End of MUXF5_inst instantiation
```

## For More Information

# MUXF5\_D

Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output

## Introduction

This design element provides a multiplexer function in a CLB slice for creating a function-of-5 lookup table or a 4-to-1 multiplexer in combination with the associated lookup tables. The local outputs (LO) from the two lookup tables are connected to the I0 and I1 inputs of the MUXF5. The S input is driven from any internal net. When Low, S selects I0. When High, S selects I1.

Outputs O and LO are functionally identical. The O output is a general interconnect. The LO output connects to other inputs in the same CLB slice. See also “MUXF5” and “MUXF5\_L”

## Logic Table

Inputs			Outputs	
S	I0	I1	O	LO
0	1	X	1	1
0	0	X	0	0
1	X	1	1	1
1	X	0	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF5_D: Slice MUX to tie two LUT4's together with general and local outputs
--           All FPGA Devices except Virtex-5
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF5_D_inst : MUXF5_D
port map (
LO => LO, -- Output of MUX to local routing
O => O,   -- Output of MUX to general routing
I0 => I0, -- Input (tie directly to the output of LUT4)

```

```
I1 => I1, -- Input (tie directly to the output of LUT4)
S => S    -- Input select to MUX
);

-- End of MUXF5_D_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF5_D: Slice MUX to tie two LUT4's together with general and local outputs
//           For use with All FPGAs except Virtex-5
// Xilinx HDL Libraries Guide, version 10.1.2

MUXF5_D MUXF5_D_inst (
  .LO(IO), // Output of MUX to local routing
  .O(O),  // Output of MUX to general routing
  .IO(IO), // Input (tie directly to the output of LUT4)
  .I1(I1), // Input (tie directly to the output of LUT4)
  .S(S)   // Input select to MUX
);

// End of MUXF5_D_inst instantiation
```

## For More Information

# MUXF6

Primitive: 2-to-1 Look-Up Table Multiplexer with General Output

## Introduction

This design element provides a multiplexer function in two slices for creating a function-of-6 lookup table or an 8-to-1 multiplexer in combination with the associated four lookup tables and two MUXF5s. The local outputs (LO) from the two MUXF5s in the CLB are connected to the I0 and I1 inputs of the MUXF6. The S input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

The variants, "MUXF6\_D" and "MUXF6\_L", provide additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

## Logic Table

Inputs			Outputs
S	I0	I1	O
0	1	X	1
0	0	X	0
1	X	1	1
1	X	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

## MUXF6\_L

Primitive: 2-to-1 Look-Up Table Multiplexer with Local Output

## Introduction

This design element provides a multiplexer function for use in creating a function-of-6 lookup table or an 8-to-1 multiplexer in combination with the associated four lookup tables and two MUXF5s. The local outputs (LO) from the two MUXF5s in the (CLB) are connected to the I0 and I1 inputs of the MUXF6. The (S) input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

The LO output connects to other inputs in the same CLB slice.

## Logic Table

Inputs			Output
S	I0	I1	LO
0	1	X	1
0	0	X	0
1	X	1	1
1	X	0	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF6_L: CLB MUX to tie two MUXF5's together with local output
-- All FPGA Devices except Virtex-5
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF6_L_inst : MUXF6_L
port map (
LO => LO, -- Output of MUX to local routing
I0 => I0, -- Input (tie to MUXF5 LO out)
I1 => I1, -- Input (tie to MUXF5 LO out)
S => S -- Input select to MUX

```

```
);  
-- End of MUXF6_L_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF6_L: CLB MUX to tie two MUXF5's together with local output  
// For use with All FPGAs except Virtex-5  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
MUXF6_L MUXF6_L_inst (  
  .LO(IO), // Output of MUX to local routing  
  .I0(I0), // Input (tie to MUXF5 LO out)  
  .I1(I1), // Input (tie to MUXF5 LO out)  
  .S(S)    // Input select to MUX  
);  
  
// End of MUXF6_L_inst instantiation
```

# MUXF7

Primitive: 2-to-1 Look-Up Table Multiplexer with General Output

## Introduction

This design element provides a multiplexer function for use in creating a function-of-7 Look-Up Table or a 16-to-1 multiplexer in combination with the associated Look-Up Tables. Local outputs (LO) of MUXF6 are connected to the I0 and I1 inputs of the MUXF7. The (S) input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

The variants, "MUXF7\_D" and "MUXF7\_L", provide additional types of outputs that can be used by different timing models for more accurate pre-layout timing estimation.

## Logic Table

Inputs			Outputs
S	I0	I1	O
0	I0	X	I0
1	X	I1	I1
X	0	0	0
X	1	1	1

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Output of MUX to general routing
I0	Input	1	Input (tie to MUXF6 LO out)
I1	Input	1	Input (tie to MUXF6 LO out)
S	Input	1	Input select to MUX

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF7: CLB MUX to tie two MUXF6's together with general output
-- Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF7_inst : MUXF7
port map (
O => O,    -- Output of MUX to general routing
I0 => I0,  -- Input (tie to MUXF6 LO out)
I1 => I1,  -- Input (tie to MUXF6 LO out)
S => S    -- Input select to MUX
);

-- End of MUXF7_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF7: CLB MUX to tie two LUT6's or MUXF6's together with general output
//      For use with Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

MUXF7 MUXF7_inst (
.O(O),    // Output of MUX to general routing
.I0(I0),  // Input (tie to MUXF6 LO out)
.I1(I1),  // Input (tie to MUXF6 LO out)
.S(S)    // Input select to MUX
);

// End of MUXF7_inst instantiation
```

# MUXF7\_D

Primitive: 2-to-1 Look-Up Table Multiplexer with Dual Output

## Introduction

This design element provides a multiplexer function for use in creating a function-of-7 Look-Up Table or a 16-to-1 multiplexer in combination with the associated Look-Up Tables. Local outputs (LO) of MUXF6 are connected to the I0 and I1 inputs of the MUXF7. The S input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

Outputs O and LO are functionally identical. The O output is a general interconnect. The LO output connects to other inputs in the same CLB slice.

## Logic Table

Inputs			Outputs	
S	I0	I1	O	LO
0	I0	X	I0	I0
1	X	I1	I1	I1
X	0	0	0	0
X	1	1	1	1

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Output of MUX to general routing
LO	Output	1	Output of MUX to local routing
I0	Input	1	Input (tie to MUXF6 LO out)
I1	Input	1	Input (tie to MUXF6 LO out)
S	Input	1	Input select to MUX

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF7_D: CLB MUX to tie two MUXF6's together with general and local outputs
-- Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF7_D_inst : MUXF7_D
port map (
LO => LO, -- Ouptut of MUX to local routing
O => O, -- Output of MUX to general routing
I0 => I0, -- Input (tie to MUXF6 LO out)
I1 => I1, -- Input (tie to MUXF6 LO out)
S => S -- Input select to MUX
);

-- End of MUXF7_D_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF7_D: CLB MUX to tie two LUT6's or MUXF6's together with general and local outputs
// For use with Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

MUXF7_D MUXF7_D_inst (
.LO(LO), // Ouptut of MUX to local routing
.O(O), // Output of MUX to general routing
.I0(I0), // Input (tie to MUXF6 LO out)
.I1(I1), // Input (tie to MUXF6 LO out)
.S(S) // Input select to MUX
);

// End of MUXF7_D_inst instantiation
```

## MUXF7\_L

Primitive: 2-to-1 Look-Up Table Multiplexer with Local Output

## Introduction

This design element provides a multiplexer function for use in creating a function-of-7 Look-Up Table or a 16-to-1 multiplexer in combination with the associated Look-Up Tables. Local outputs (LO) of MUXF6 are connected to the I0 and I1 inputs of the MUXF7. The S input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

The LO output connects to other inputs in the same CLB slice.

## Logic Table

Inputs			Output
S	I0	I1	LO
0	I0	X	I0
1	X	I1	I1
X	0	0	0
X	1	1	1

## Port Descriptions

Port	Direction	Width	Function
LO	Output	1	Output of MUX to local routing
I0	Input	1	Input (tie to MUXF6 LO out)
I1	Input	1	Input (tie to MUXF6 LO out)
S	Input	1	Input select to MUX

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF7_L: CLB MUX to tie two MUXF6's together with local output
-- Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF7_L_inst : MUXF7_L
port map (
LO => LO, -- Output of MUX to local routing
IO => IO, -- Input (tie to MUXF6 LO out)
I1 => I1, -- Input (tie to MUXF6 LO out)
S => S   -- Input select to MUX
);

-- End of MUXF7_L_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF7_L: CLB MUX to tie two LUT6's or MUXF6's together with local output
//           For use with Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

MUXF7_L MUXF7_L_inst (
.LO(LO), // Output of MUX to local routing
.I0(IO), // Input (tie to MUXF6 LO out)
.I1(I1), // Input (tie to MUXF6 LO out)
.S(S)   // Input select to MUX
);

// End of MUXF7_L_inst instantiation
```

## For More Information

# MUXF8

Primitive: 2-to-1 Look-Up Table Multiplexer with General Output

## Introduction

This design element provides a multiplexer function in eight slices for creating a function-of-8 Look-Up Table or a 32-to-1 multiplexer in combination with the associated Look-Up Tables, MUXF5s, MUXF6s, and MUXF7s. Local outputs (LO) of MUXF7 are connected to the I0 and I1 inputs of the MUXF8. The S input is driven from any internal net. When Low, (S) selects I0. When High, (S) selects I1.

## Logic Table

Inputs			Outputs
S	I0	I1	O
0	I0	X	I0
1	X	I1	I1
X	0	0	0
X	1	1	1

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Output of MUX to general routing
I0	Input	1	Input (tie to MUXF7 LO out)
I1	Input	1	Input (tie to MUXF7 LO out)
S	Input	1	Input select to MUX

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- MUXF8: CLB MUX to tie two MUXF7's together with general output
-- Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

MUXF8_inst : MUXF8
port map (
O => O,    -- Output of MUX to general routing
I0 => I0,  -- Input (tie to MUXF7 LO out)
I1 => I1,  -- Input (tie to MUXF7 LO out)
S => S    -- Input select to MUX
);

-- End of MUXF8_inst instantiation
```

## Verilog Instantiation Template

```
// MUXF8: CLB MUX to tie two MUXF7's together with general output
//      For use with Virtex-II/II-Pro/4/5 and Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

MUXF8 MUXF8_inst (
.O(O),    // Output of MUX to general routing
.I0(I0),  // Input (tie to MUXF7 LO out)
.I1(I1),  // Input (tie to MUXF7 LO out)
.S(S)     // Input select to MUX
);

// End of MUXF8_inst instantiation
```

# OBUF

Primitive: Output Buffer

## Introduction

This design element is a simple output buffer used to drive output signals to the FPGA device pins that do not need to be 3-stated (constantly driven). Either an OBUF, OBUFT, OBUFDS, or OBUFTDS must be connected to every output port in the design.

This element isolates the internal circuit and provides drive current for signals leaving a chip. It exists in input/output blocks (IOB). Its output (O) is connected to an OPAD or an IOPAD. The interface standard used by this element is LVTTTL. Also, this element has selectable drive and slew rates using the DRIVE and SLOW or FAST constraints. The defaults are DRIVE=12 mA and SLOW slew.

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Output of OBUF to be connected directly to top-level output port.
I	Input	1	Input of OBUF. Connect to the logic driving the output port.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- OBUF: Single-ended Output Buffer
--     All devices
-- Xilinx HDL Libraries Guide, version 10.1.2

OBUF_inst : OBUF
    
```

```
generic map (  
  DRIVE => 12,  
  IOSTANDARD => "DEFAULT",  
  SLEW => "SLOW")  
port map (  
  O => O,      -- Buffer output (connect directly to top-level port)  
  I => I       -- Buffer input  
);  
  
-- End of OBUF_inst instantiation
```

## Verilog Instantiation Template

```
// OBUF: Single-ended Output Buffer  
// All devices  
// Xilinx HDL Libraries Guide, version 10.1.2  
  
OBUF #(  
  .DRIVE(12), // Specify the output drive strength  
  .IOSTANDARD("DEFAULT"), // Specify the output I/O standard  
  .SLEW("SLOW") // Specify the output slew rate  
) OBUF_inst (  
  .O(O), // Buffer output (connect directly to top-level port)  
  .I(I) // Buffer input  
);  
  
// End of OBUF_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# OBUFDS

Primitive: Differential Signaling Output Buffer

## Introduction

This design element is a single output buffer that supports low-voltage, differential signaling (1.8 v CMOS). OBUFDS isolates the internal circuit and provides drive current for signals leaving the chip. Its output is represented as two distinct ports (O and OB), one deemed the "master" and the other the "slave." The master and the slave are opposite phases of the same logical signal (for example, MYNET and MYNETB).

## Logic Table

Inputs		Outputs
I	O	OB
0	0	1
1	1	0

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Diff_p output (connect directly to top level port)
OB	Input	1	Diff_n output (connect directly to top level port)
I	Input	1	Buffer input

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- OBUFDS: Differential Output Buffer
--           Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

OBUFDS_inst : OBUFDS
generic map (
  IOSTANDARD => "DEFAULT")
port map (
  O => O,      -- Diff_p output (connect directly to top-level port)
  OB => OB,    -- Diff_n output (connect directly to top-level port)
  I => I      -- Buffer input
);

-- End of OBUFDS_inst instantiation
```

## Verilog Instantiation Template

```
// OBUFDS: Differential Output Buffer
//           Virtex-II/II-Pro/4/5, Spartan-3/3E/3A
// Xilinx HDL Libraries Guide, version 10.1.2

OBUFDS #(
  .IOSTANDARD("DEFAULT") // Specify the output I/O standard
) OBUFDS_inst (
  .O(O),      // Diff_p output (connect directly to top-level port)
  .OB(OB),   // Diff_n output (connect directly to top-level port)
  .I(I)      // Buffer input
);

// End of OBUFDS_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# OBUFT

Primitive: 3-State Output Buffer with Active Low Output Enable

## Introduction

This design element is a single, 3-state output buffer with input I, output O, and active-Low output enables (T). This element uses the LVTTTL standard and has selectable drive and slew rates using the DRIVE and SLOW or FAST constraints. The defaults are DRIVE=12 mA and SLOW slew.

When T is Low, data on the inputs of the buffers is transferred to the corresponding outputs. When T is High, the output is high impedance (off or Z state). OBUFTs are generally used when a single-ended output is needed with a 3-state capability, such as the case when building bidirectional I/O.

## Logic Table

Inputs		Outputs
T	I	O
1	X	Z
0	I	F

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Buffer output (connect directly to top-level port)
I	Input	1	Buffer input
T	Input	1	3-state enable input

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- OBUFT: Single-ended 3-state Output Buffer
--      All devices
-- Xilinx HDL Libraries Guide, version 10.1.2

OBUFT_inst : OBUFT
generic map (
DRIVE => 12,
IOSTANDARD => "DEFAULT",
SLEW => "SLOW")
port map (
O => O,      -- Buffer output (connect directly to top-level port)
I => I,      -- Buffer input
T => T      -- 3-state enable input
);

-- End of OBUFT_inst instantiation
```

## Verilog Instantiation Template

```
// OBUFT: Single-ended 3-state Output Buffer
//      All devices
// Xilinx HDL Libraries Guide, version 10.1.2

OBUFT #(
.DRIVE(12), // Specify the output drive strength
.IOSTANDARD("DEFAULT"), // Specify the output I/O standard
.SLEW("SLOW") // Specify the output slew rate
) OBUFT_inst (
.O(O), // Buffer output (connect directly to top-level port)
.I(I), // Buffer input
.T(T) // 3-state enable input
);

// End of OBUFT_inst instantiation
```

## For More Information

- See the [Virtex-II User Guide](#).
- See the [Virtex-II Data Sheets](#).

# OBUFTDS

Primitive: 3-State Output Buffer with Differential Signaling, Active-Low Output Enable

## Introduction

This design element is an output buffer that supports low-voltage, differential signaling. For the OBUFTDS, a design level interface signal is represented as two distinct ports (O and OB), one deemed the "master" and the other the "slave." The master and the slave are opposite phases of the same logical signal (for example, MYNET\_P and MYNET\_N).

## Logic Table

Inputs		Outputs	
I	T	O	OB
X	1	Z	Z
0	0	0	1
1	0	1	0

## Port Descriptions

Port	Direction	Width	Function
O	Output	1	Diff_p output (connect directly to top level port)
OB	Output	1	Diff_n output (connect directly to top level port)
I	Input	1	Buffer input
T	Input	1	3-state enable input

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
IOSTANDARD	String	See Data Sheet	"DEFAULT"	Assigns an I/O standard to the element.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- OBUFTDS: Differential 3-state Output Buffer
--           Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

OBUFTDS_inst : OBUFTDS
generic map (
  IOSTANDARD => "DEFAULT")
port map (
  O => O,      -- Diff_p output (connect directly to top-level port)

## OFDDRCPE

Primitive: Dual Data Rate Output D Flip-Flop with Clock Enable and Asynchronous Preset and Clear

### Introduction

This design element is a dual data rate (DDR) output D flip-flop with clock enable (CE) and asynchronous preset (PRE) and clear (CLR). It consists of one output buffer and one dual data rate flip-flop (FDDRCPE). When the asynchronous PRE is High and CLR is Low, the Q output is preset High.

When CLR is High, Q is set Low. Data on the D0 input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the Low-to-High C0 clock transition. Data on the D1 input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the Low-to-High C1 clock transition. The INIT attribute does not apply to OFDDRCPE components.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

### Logic Table

Inputs							Outputs
C0	C1	CE	D0	D1	CLR	PRE	Q
X	X	X	X	X	1	0	0
X	X	X	X	X	0	1	1
X	X	X	X	X	1	1	0
X	X	0	X	X	0	0	No Change

# OFDDRSE

Primitive: Dual Data Rate Output D Flip-Flop with Synchronous Reset and Set and Clock Enable

## Introduction

This design element is a dual data rate (DDR) output D flip-flop with synchronous reset (R) and set (S) and clock enable (CE). It consists of one output buffer and one dual data rate flip-flop (FDDRSE).

On a Low-to-High clock transition (C0 or C1), a High R input resets the Q output Low; a Low R input with a High S input sets Q High. When both R and S are Low and clock enable is High, data on the D0 input is loaded into the flip-flop on a Low-to-High C0 clock transition and data on the D1 input is loaded into the flip-flop on a Low-to-High C1 clock transition.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate *STARTUP\_architecture* symbol.

The INIT attribute does not apply to this design element.

## Logic Table

Inputs							Outputs
C0	C1	CE	D0	D1	R	S	Q
↑	X	X	X	X	1	0	0

# OFDDRTCPE

Primitive: Dual Data Rate D Flip-Flop with Active-Low 3-State Output Buffer, Clock Enable, and Asynchronous Preset and Clear

## Introduction

This design element is a dual data rate (DDR) D flip-flop with clock enable (CE) and asynchronous preset and clear whose output is enabled by a 3-state buffer. It consists of a dual data rate flip-flop (FDDRCPE) and a 3-state output buffer (OBUFT). The data output (O) of the flip-flop is connected to the input of the output buffer (OBUFT). The output of the OBUFT is connected to an OPAD or IOPAD.

When the active-Low enable input (T) is Low, output is enabled and the data on the flip-flop's Q output appears on the OBUFT's O output. When the asynchronous PRE is High and CLR is Low, the O output is preset High. When CLR is High, O is set Low. Data on the D0 input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the Low-to-High C0 clock transition. Data on the D1 input is loaded into the flip-flop when PRE and CLR are Low and CE is High on the Low-to-High C1 clock transition.

When T is High, outputs are high impedance (Off). When CE is Low and T is Low, the outputs do not change.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

The INIT attribute does not apply to this design element.

# OFDDRTRSE

Primitive: Dual Data Rate D Flip-Flop with Active -Low 3-State Output Buffer, Synchronous Reset and Set, and Clock Enable

## Introduction

This design element is a dual data rate (DDR) D flip-flop with clock enable (CE) and synchronous reset and set whose output is enabled by a 3-state buffer. It consists of a dual data rate flip-flop (FDDRSE) and a 3-state output buffer (OBUFT). The data output (O) of the flip-flop is connected to the input of the output buffer (OBUFT). The output of the OBUFT is connected to an OPAD or IOPAD.

When the active-Low enable input (T) is Low, output is enabled and the data on the flip-flop's Q output appears on the OBUFT's O output. On a Low-to-High clock transition (C0 or C1), a High R input resets the Q output Low; a Low R input with a High S input sets O High. When both R and S are Low and clock enable is High, data on the D0 input is loaded into the flip-flop on a Low-to-High C0 clock transition and data on the D1 input is loaded into the flip-flop on a Low-to-High C1 clock transition.

When T is High, outputs are high impedance (Off). When CE is Low and T is Low, the outputs do not change.

This flip-flop is asynchronously cleared, outputs Low, when power is applied. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate *STARTUP\_architecture* symbol.

The INIT attribute does not apply to this design elements components

## ORCY

Primitive: OR with Carry Logic

## Introduction

This element is a special OR with general O output that generates faster and smaller arithmetic functions.

Each Virtex-II, Virtex-II Pro, and Virtex-II Pro X slice contains a dedicated 2-input OR gate that ORs together carry out values for a series of horizontally adjacent carry chains. The OR gate gets one input external to the slice and the other input from the output of the high order carry mux. The OR gate's output drives the next slice's OR gate horizontally across the die.

Only MUXCY outputs can drive the signal on the CI pin. Only this design elements outputs or logic zero can drive the I pin.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;

# RAM128X1S

Primitive: 128-Deep by 1-Wide Static Synchronous RAM

## Introduction

This element is a 128-word by 1-bit static random access memory with synchronous write capability. When the write enable is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data input (D) into the word selected by the 7-bit address (A6 - A0). This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pin (O) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can initialize RAM128X1S during configuration using the INIT attribute.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D	O
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D	D
1 (read)	↓	X	Data

Data = word addressed by bits A6 – A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended

Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 128-Bit Value	All zeros	Initializes ROMs, RAMs, registers, and look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

# RAM128X1S\_1

Primitive: 128-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock

## Introduction

This element is a 128-word by 1-bit static random access memory with synchronous write capability. When the write enable is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any negative transition on WCLK loads the data on the data input (D) into the word selected by the 7-bit address (A6 – A0). For predictable performance, address and data inputs must be stable before a High-to-Low WCLK transition. This RAM block assumes an active-Low WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pin (O) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can initialize RAM128X1S\_1 during configuration using the INIT attribute.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D	O

# RAM16X1D

Primitive: 16-Deep by 1-Wide Static Dual Port Synchronous RAM

## Introduction

This element is a 16-word by 1-bit static dual port random access memory with synchronous write capability. The device has two address ports: the read address (DPRA3–DPRA0) and the write address (A3–A0). These two address ports are asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected.

When WE is High, any positive transition on (WCLK) loads the data on the data input (D) into the word selected by the 4-bit write address. For predictable performance, write address and data inputs must be stable before a Low-to-High (WCLK) transition. This RAM block assumes an active-High (WCLK). (WCLK) can be active-High or active-Low. Any inverter placed on the (WCLK) input net is absorbed into the block.

The SPO output reflects the data in the memory cell addressed by A3 – A0. The DPO output reflects the data in the memory cell addressed by DPRA3–DPRA0.

**Note** The write process is not affected by the address on the read address port.

You can use the INIT attribute to directly specify an initial value. The value must be a hexadecimal number, for example, INIT=ABAC. If the INIT attribute is not specified, the RAM is initialized with all zeros.

## Logic Table

Mode selection is shown in the following logic table:

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d
1 (read)	1	X	data_a	data_d
1 (write)	↑	D	D	data_d

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
1 (read)	↓	X	data_a	data_d
data_a = word addressed by bits A3-A0				
data_d = word addressed by bits DPRA3-DPRA0				

## Design Entry Method

# RAM16X1D\_1

Primitive: 16-Deep by 1-Wide Static Dual Port Synchronous RAM with Negative-Edge Clock

## Introduction

This is a 16-word by 1-bit static dual port random access memory with synchronous write capability and negative-edge clock. The device has two separate address ports: the read address (DPRA3–DPRA0) and the write address (A3–A0). These two address ports are asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction.

When the write enable (WE) is set to Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When (WE) is High, any negative transition on (WCLK) loads the data on the data input (D) into the word selected by the 4-bit write address. For predictable performance, write address and data inputs must be stable before a High-to-Low WCLK transition. This RAM block assumes an active-High (WCLK). (WCLK) can be active-High or active-Low. Any inverter placed on the (WCLK) input net is absorbed into the block.

You can initialize RAM16X1D\_1 during configuration using the INIT attribute.

The SPO output reflects the data in the memory cell addressed by A3–A0. The DPO output reflects the data in the memory cell addressed by DPRA3–DPRA0.

**Note** The write process is not affected by the address on the read address port.

## Logic Table

Mode selection is shown in the following logic table:

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d
1 (read)	1	X	data_a	data_d
1 (write)	↓	D	D	data_d
1 (read)	↑	X	data_a	data_d

data\_a = word addressed by bits A3 – A0  
data\_d = word addressed by bits DPRA3-DPRA0

## Port Descriptions

Port	Direction	Width	Function
DPO	Output	1	Read-only 1-Bit data output
SPO	Output	1	R/W 1-Bit data output
A0	Input	1	R/W address[0] input
A1	Input	1	R/W address[1] input
A2	Input	1	R/W address[2] input
A3	Input	1	R/W address[3] input
D	Input	1	Write 1-Bit data input
DPRA0	Input	1	Read-only address[0] input
DPRA1	Input	1	Read-only address[1] input
DPRA2	Input	1	Read-only address[2] input
DPRA3	Input	1	Read-only address[3] input
WCLK	Input	1	Write clock input
WE	Input	1	Write enable input

# RAM16X2S

Primitive: 16-Deep by 2-Wide Static Synchronous RAM

## Introduction

This element is a 16-word by 2-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data input (D1–D0) into the word selected by the 4-bit address (A3–A0). For predictable performance, address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pins (O1–O0) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can use the INIT\_x properties to specify the initial contents of a Virtex-4 wide RAM. INIT\_00 initializes the RAM cells corresponding to the O0 output, INIT\_01 initializes the cells corresponding to the O1 output, etc. For example, a RAM16X2S instance is initialized by INIT\_00 and INIT\_01 containing 4 hex characters each. A RAM16X8S instance is initialized by eight properties INIT\_00 through INIT\_07 containing 4 hex characters each. A RAM64x2S instance is completely initialized by two properties INIT\_00 and INIT\_01 containing 16 hex characters each.

Except for Virtex-4 devices, the initial contents of this element cannot be specified directly.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D1-D0	O1-O0
0 (read)	X	X	Data
1(read)	0	X	Data
1(read)	1	X	Data
1(write)	↑	D1-D0	D1-D0
1 (read)	↓	X	Data
Data = word addressed by bits A3 – A0			

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No

# RAM16X4S

Primitive: 16-Deep by 4-Wide Static Synchronous RAM

## Introduction

This element is a 16-word by 4-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data input (D3 – D0) into the word selected by the 4-bit address (A3 – A0). For predictable performance, address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pins (O3 – O0) is the data that is stored in the RAM at the location defined by the values on the address pins.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D3 – D0	O3 – O0
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D3-D0	D3-D0
1 (read)	↓	X	Data

Data = word addressed by bits A3 – A0.

## Design Entry Method

Instantiation	Yes
Inference	Recommended

Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 to INIT_03	Hexadecimal	Any 16-Bit Value	All zeros	INIT for bit 0 of RAM

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

# RAM16X8S

Primitive: 16-Deep by 8-Wide Static Synchronous RAM

## Introduction

This element is a 16-word by 8-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on data inputs (D7–D0) into the word selected by the 4-bit address (A3–A0). For predictable performance, address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pins (O7–O0) is the data that is stored in the RAM at the location defined by the values on the address pins.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D7-D0	O7-O0
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D7-D0	D7-D0
1 (read)	↓	X	Data

Data = word addressed by bits A3–A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended

# RAM32X1D

Primitive: 32-Deep by 1-Wide Dual Static Port Synchronous RAM

## Introduction

The design element is a 32-word by 1-bit static dual port random access memory with synchronous write capability. The device has two separate address ports: the read address (DPRA4 – DPRA0) and the write address (A4 – A0). These two address ports are completely asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data input (D) into the word selected by the 5-bit write address. For predictable performance, write address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block. You can initialize RAM32X1D during configuration using the INIT attribute. Mode selection is shown in the following logic table.

The SPO output reflects the data in the memory cell addressed by A4 – A0. The DPO output reflects the data in the memory cell addressed by DPRA4 – DPRA0. The write process is not affected by the address on the read address port.

## Logic Table

Inputs			Outputs	
WE (Mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d
1 (read)	1	X	data_a	data_d
1 (write)	↑	D	D	data_d
1 (read)	↓	X	data_a	data_d

## Design Entry Method

Instantiation	Yes
Inference	Recommended

Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Descriptions
INIT	Hexadecimal	Any 32-Bit Value	All Zeros	Initializes ROMs, RAMs, registers, and look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;

# RAM32X1D\_1

Primitive: 32-Deep by 1-Wide Static Dual Port Synchronous RAM with Negative-Edge Clock

## Introduction

This design element is a 32-word by 1-bit static dual port random access memory with synchronous write capability and a negative-edge clock. The device has two separate address ports: the read address (DPRA4 – DPRA0) and the write address (A4 – A0). These two address ports are completely asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction.

When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any negative transition on WCLK loads the data on the data input (D) into the word selected by the 5-bit write address. For predictable performance, write address and data inputs must be stable before a High-to-Low WCLK transition. This RAM block assumes an active-Low WCLK. WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

You can initialize this design element during configuration using the INIT attribute.

The SPO output reflects the data in the memory cell addressed by A4 – A0. The DPO output reflects the data in the memory cell addressed by DPRA4 – DPRA0.

**Note** The write process is not affected by the address on the read address port.

## Logic Table

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d
1 (read)	1	X	data_a	data_d
1 (write)	↓	D	D	data_d
1 (read)	↑	X	data_a	data_d

data\_a = word addressed by bits A4-A0  
 data\_d = word addressed by bits DPRA4-DPRA0

## Design Entry Method

This design element is only for use in schematics.

## Available Attributes

# RAM32X2S

Primitive: 32-Deep by 2-Wide Static Synchronous RAM

## Introduction

The design element is a 32-word by 2-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When (WE) is High, any positive transition on (WCLK) loads the data on the data input (D1-D0) into the word selected by the 5-bit address (A4-A0). For predictable performance, address and data inputs must be stable before a Low-to-High (WCLK) transition. This RAM block assumes an active-High (WCLK). However, (WCLK) can be active-High or active-Low. Any inverter placed on the (WCLK) input net is absorbed into the block. The signal output on the data output pins (O1-O0) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can use the INIT\_00 and INIT\_01 properties to specify the initial contents of RAM32X2S.

## Logic Table

Inputs			Outputs
WE (Mode)	WCLK	D	O0-O1
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D1-D0	D1-D0
1 (read)	↓	X	Data

Data = word addressed by bits A4 A0

## Design Entry Method

# RAM32X4S

Primitive: 32-Deep by 4-Wide Static Synchronous RAM

## Introduction

This design element is a 32-word by 4-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data inputs (D3-D0) into the word selected by the 5-bit address (A4-A0). For predictable performance, address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pins (O3-O0) is the data that is stored in the RAM at the location defined by the values on the address pins.

## Logic Table

Inputs			Outputs
WE	WCLK	D3-D0	O3-O0
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D3-D0	D3-D0
1 (read)	↓	X	Data

Data = word addressed by bits A4-A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended

Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00	Hexadecimal	Any 32-Bit Value	All zeros	INIT for bit 0 of RAM.
INIT_01	Hexadecimal	Any 32-Bit Value	All zeros	INIT for bit 1 of RAM.
INIT_02	Hexadecimal	Any 32-Bit Value	All zeros	INIT for bit 2 of RAM.
INIT_03	Hexadecimal	Any 32-Bit Value	All zeros	INIT for bit 3 of RAM.

# RAM64X1D

Primitive: 64-Deep by 1-Wide Dual Port Static Synchronous RAM

## Introduction

This design element is a 64-word by 1-bit static dual port random access memory with synchronous write capability. The device has two separate address ports: the read address (DPRA5–DPRA0) and the write address (A5–A0). These two address ports are completely asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected.

When WE is High, any positive transition on WCLK loads the data on the data input (D) into the word selected by the 6-bit (A0–A5) write address. For predictable performance, write address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The SPO output reflects the data in the memory cell addressed by A5–A0. The DPO output reflects the data in the memory cell addressed by DPRA5–DPRA0.

**Note** The write process is not affected by the address on the read address port.

## Logic Table

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d
1 (read)	1	X	data_a	data_d
1 (write)	↑	D	D	data_d
1 (read)	↓	X	data_a	data_d

data\_a = word addressed by bits A5–A0

data\_d = word addressed by bits DPRA5–DPRA0

# RAM64X1D\_1

Primitive: 64-Deep by 1-Wide Dual Port Static Synchronous RAM with Negative-Edge Clock

## Introduction

This design element is a 64-word by 1-bit static dual port random access memory with synchronous write capability and a negative-edge clock. The device has two separate address ports: the read address (DPRA5–DPRA0) and the write address (A5–A0). These two address ports are completely asynchronous. The read address controls the location of the data driven out of the output pin (DPO), and the write address controls the destination of a valid write transaction.

When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any negative transition on WCLK loads the data on the data input (D) into the word selected by the 6-bit (A0–A5) write address. For predictable performance, write address and data inputs must be stable before a High-to-Low WCLK transition. This RAM block assumes an active-Low WCLK. WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

You can initialize this design element during configuration using the INIT attribute. The SPO output reflects the data in the memory cell addressed by A5–A0. The DPO output reflects the data in the memory cell addressed by DPRA5–DPRA0.

**Note** The write process is not affected by the address on the read address port.

## Logic Table

Inputs			Outputs	
WE (mode)	WCLK	D	SPO	DPO
0 (read)	X	X	data_a	data_d
1 (read)	0	X	data_a	data_d

# RAM64X1S

Primitive: 64-Deep by 1-Wide Static Synchronous RAM

## Introduction

This design element is a 64-word by 1-bit static random access memory (RAM) with synchronous write capability. When the write enable is set Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is set High, any positive transition on WCLK loads the data on the data input (D) into the word selected by the 6-bit address (A5 - A0). This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pin (O) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can initialize this element during configuration using the INIT attribute.

## Logic Table

Mode selection is shown in the following logic table

Inputs			Outputs
WE (mode)	WCLK	D	O
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D	D
1 (read)	↓	X	Data

Data = word addressed by bits A5 – A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 64-Bit Value	All zeros	Initializes ROMs, RAMs, registers, and look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;

# RAM64X1S\_1

Primitive: 64-Deep by 1-Wide Static Synchronous RAM with Negative-Edge Clock

## Introduction

This design element is a 64-word by 1-bit static random access memory with synchronous write capability. When the write enable is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When (WE) is High, any negative transition on (WCLK) loads the data on the data input (D) into the word selected by the 6-bit address (A5 – A0). For predictable performance, address and data inputs must be stable before a High-to-Low (WCLK) transition. This RAM block assumes an active-Low (WCLK). However, (WCLK) can be active-High or active-Low. Any inverter placed on the (WCLK) input net is absorbed into the block.

The signal output on the data output pin (O) is the data that is stored in the RAM at the location defined by the values on the address pins.

You can initialize this element during configuration using the INIT attribute.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D	O
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↓	D	D
1 (read)	↑	X	Data

Data = word addressed by bits A5 – A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 64-Bit Value	All zeros	Initializes ROMs, RAMs, registers, and look-up tables.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# RAM64X2S

Primitive: 64-Deep by 2-Wide Static Synchronous RAM

## Introduction

This design element is a 64-word by 2-bit static random access memory with synchronous write capability. When the write enable (WE) is Low, transitions on the write clock (WCLK) are ignored and data stored in the RAM is not affected. When WE is High, any positive transition on WCLK loads the data on the data input (D1–D0) into the word selected by the 6-bit address (A5–A0). For predictable performance, address and data inputs must be stable before a Low-to-High WCLK transition. This RAM block assumes an active-High WCLK. However, WCLK can be active-High or active-Low. Any inverter placed on the WCLK input net is absorbed into the block.

The signal output on the data output pins (O1–O0) is the data that is stored in the RAM at the location defined by the values on the address pins. You can use the INIT\_00 and INIT\_01 properties to specify the initial contents of this design element.

## Logic Table

Inputs			Outputs
WE (mode)	WCLK	D0–D1	O0–O1
0 (read)	X	X	Data
1 (read)	0	X	Data
1 (read)	1	X	Data
1 (write)	↑	D1–D0	D1–D0
1 (read)	↓	X	Data

Data = word addressed by bits A5–A0

## Design Entry Method

Instantiation	Yes
Inference	Recommended

Coregen and wizards	No
Macro support	No

# RAMB16\_S1

Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 1-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
16384	1	-	-	(13:0)	(0:0)	-

The enable EN pin controls read, write, and reset for Port A. When EN is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When EN is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When EN is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when EN and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL	SRVAL	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL	SRVAL	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change(a) RAM (addr)(b) data(c)	No Change(a) RAM (addr)(b) pdata(c)	RAM (addr)=>data	RAM (addr)=>pdata

GSR=Global Set Reset signal  
 INIT=Value specified by the INIT attribute for data memory. Default is all zeros.  
 SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
 (a) WRITE\_MODE=NO\_CHANGE  
 (b) WRITE\_MODE=READ\_FIRST  
 (c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;
```

```

# RAMB16\_S1\_S1

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_A	INIT_A	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL_A	SRVAL_A	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL_A	SRVAL_A	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDRA	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change1, RAM(addr)2, data3	No Change1, RAM(addr)2, pdata3	RAM(addr) =>data	RAM(addr) =>pdata
<p>GSR=Global Set Reset</p> <p>INIT_A=Value specified by the INIT_A attribute for output register. Default is all zeros.</p> <p>SRVAL_A=register value.</p> <p>addr=RAM address.</p> <p>RAM(addr)=RAM contents at address ADDR.</p> <p>data=RAM input data.</p> <p>pdata=RAM parity data.</p> <p>1WRITE_MODE_A=NO_CHANGE.</p> <p>2WRITE_MODE_A=READ_FIRST.</p> <p>3WRITE_MODE_A=WRITE_FIRST.</p>											

Truth Table B

Inputs								Outputs			
GSR	ENB	SSRB	WEB	CLKB	ADDRB	DIB	DIPB	DOB	DOPB	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_B	INIT_B	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL_B	SRVAL_B	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL_B	SRVAL_B	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change
0	1	0	1	↑	addr	data	pdata	No Change1, RAM(addr) =>data, data3	No Change1, RAM(addr) =>data, pdata3	RAM(addr) =>data	RAM(addr) =>pdata

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Component	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S1_S1	16384 x 1	-	(13:0)	(0:0)	-	16384 x 1	-	(13:0)	(0:0)	-
(a) Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																			
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																		
4	4096	<--	7			6			5			4			3			2			1			0												
8	2048	<--	3						2					1						0																
16	1024	<--	1											0

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																			
1	2048	<----	3							2					1																				0	
2	1024	<----	1												0																					
4	512	<----	0																																	

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.

Attribute	Type	Allowed Values	Default	Description
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

```

# RAMB16\_S1\_S18

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 18-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Component	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S1_S18	16384 x 1	-	(13:0)	(0:0)	-	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)
(a) Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRB, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																	
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
4	4096	<--	7	6	5	4	3	2	1	0																								
8	2048	<--	3	2	1	0																												
16	1024	<--	1	0																														
32	512	<--	0																															

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses															
1	2048	<----	3	2	1	0										
2	1024	<----	1	0												
4	512	<----	0													

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- RAMB16_S1_S18: Virtex-II/II-Pro, Spartan-3/3E 16k/1k x 1/16 + 0/2 Parity bits Dual-Port RAM

# RAMB16\_S1\_S2

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 2-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR	DIA	DIPA	DOA	DOPA	RAM Contents

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S1_S2	16384 x 1	-	(13:0)	(0:0)	-	8192 x 2	-	(12:0)	(1:0)	-
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

#### Address Mapping

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the "Port Address Mapping for Data" table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in "Port Address Mapping for Parity" table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables show address mapping for each port width.

#### Port Address Mapping for Data

Data Width	Port Data Addresses																																				
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
2	8192	<--	15		14		13		12		11		10		9		8		7		6		5		4		3		2		1		0				
4	4096	<--	7				6				5				4				3				2				1				0						
8	2048	<--	3								2								1								0										
16	1024	<--	1																0																		
32	512	<--	0																																		

#### Port Address Mapping for Parity

Parity Width	Port Parity Addresses																																					
1	2048	<-----	3							2					1																					0		
2	1024	<-----	1												0																							
4	512	<-----	0																																			

#### Initializing Memory Contents of a Dual-Port RAMB16

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

#### Initializing the Output Register of a Dual-Port RAMB16

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.

Attribute	Type	Allowed Values	Default	Description
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S1\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Component	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S1_S36	16384 x 1	-	(13:0)	(0:0)	-	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)
(a) Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S1_S4	16384 x 1	-	(13:0)	(0:0)	-	4096 x 4	-	(11:0)	(3:0)	-
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_ _CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_ X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# RAMB16\_S1\_S9

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 1-bit and 9-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents

<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.  
<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																	
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

16	1024	<--	1																0															
32	512	<--	0																															

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																		
1	2048	<-----	3											2																				0	
2	1024	<-----	1																																0
4	512	<-----	0																																

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# RAMB16\_S18

Primitive: 16K-bit Data + 2K-bit Parity Memory, Single-Port Synchronous Block RAM with 18-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
1024	16	1024	2	(9:0)	(15:0)	(1:0)

The enable EN pin controls read, write, and reset for Port A. When EN is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When EN is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When EN is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when EN and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change

GSR=Global Set Reset signal  
 INIT=Value specified by the INIT attribute for data memory. Default is all zeros.  
 SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
 (a) WRITE\_MODE=NO\_CHANGE  
 (b) WRITE\_MODE=READ\_FIRST  
 (c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;
```

# RAMB16\_S18\_S18

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 18-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S18_S18	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# RAMB16\_S18\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 18-bit and 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR <sub>A</sub>	DIA	DIPA	DOA	DOPA	RAM Contents

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S18_S36	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

### Address Mapping

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the "Port Address Mapping for Data" table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in "Port Address Mapping for Parity" table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables shows address mapping for each port width.

### Port Address Mapping for Data

Data Width	Port Data Addresses																																			
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																		
4	4096	<--	7			6			5			4			3			2			1			0												
8	2048	<--	3						2					1						0																
16	1024	<--	1											0																						
32	512	<--	0																																	

### Port Address Mapping for Parity

Parity Width	Port Parity Addresses																																					
1	2048	<-----	3								2												1													0		
2	1024	<-----	1																				0															
4	512	<-----	0																																			

### Initializing Memory Contents of a Dual-Port RAMB16

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register of a Dual-Port RAMB16

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# RAMB16\_S2

Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 2-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
8192	2	-	-	(12:0)	(1:0)	-

The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL	SRVAL	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL	SRVAL	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change(a) RAM (addr)(b) data(c)	No Change(a) RAM (addr)(b) pdata(c)	RAM (addr)=>data	RAM (addr)=>pdata

GSR=Global Set Reset signal  
 INIT=Value specified by the INIT attribute for data memory. Default is all zeros.  
 SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
 (a) WRITE\_MODE=NO\_CHANGE  
 (b) WRITE\_MODE=READ\_FIRST  
 (c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- RAMB16_S2: Virtex-II/II-Pro, Spartan-3/3E 8k x 2 Single-Port RAM
```

```

# RAMB16\_S2\_S18

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 18-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S2_S18	8192 x 2	-	(12:0)	(1:0)	-	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																				
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2	1024	<-----	1													0																						
4	512	<-----	0																																			

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S2\_S2

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S2_S2	8192 x 2	-	(12:0)	(1:0)	-	8192 x 2	-	(12:0)	(1:0)	-

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																		
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																			
1	2048	<-----	3								2																								0	
2	1024	<-----	1																																	0
4	512	<-----	0																																	

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- RAMB16_S2_S2: Virtex-II/II-Pro, Spartan-3/3E 8k x 2 Dual-Port RAM
-- Xilinx HDL Libraries Guide, version 10.1.2

# RAMB16\_S2\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

GSR=Global Set Reset.  
 INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.  
 SRVAL\_B=register value.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
<sup>1</sup>WRITE\_MODE\_B=NO\_CHANGE.  
<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.  
<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S2_S36	8192 x 2	-	(12:0)	(1:0)	-	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																		
	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### Port Address Mapping for Parity

Parity Width	Port Parity Addresses													
	2048	<-----	3				2				1			0
1	1024	<-----	1								0			
4	512	<-----	0											

#### Initializing Memory Contents of a Dual-Port RAMB16

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

#### Initializing the Output Register of a Dual-Port RAMB16

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The "Port A and Port B Conflict Resolution" section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

*WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE*

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.

Attribute	Type	Allowed Values	Default	Description
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

# RAMB16\_S2\_S4

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 4-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells (a)	Parity Cells (a)	Address Bus	Data Bus	Parity Bus	Data Cells (a)	Parity Cells (a)	Address Bus	Data Bus	Parity Bus
RAMB16_S2_S4	8192 x 2	-	(12:0)	(1:0)	-	4096 x 4	-	(11:0)	(3:0)	-
(a) Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																			
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
2	8192	<--	15		14		13		12		11		10		9		8		7		6		5		4		3		2		1		0			
4	4096	<--	7				6					5				4					3					2					1				0	
8	2048	<--	3												2																			0		
16	1024	<--	1																																	
32	512	<--	0																																	

### Port Address Mapping for Parity

Parity Width	Port Parity Addresses																
1	2048	<-----	3					2					1				0
2	1024	<-----	1										0				
4	512	<-----	0														

#### Initializing Memory Contents of a Dual-Port RAMB16

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

#### Initializing the Output Register of a Dual-Port RAMB16

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The "Port A and Port B Conflict Resolution" section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

*WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE*

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.

Attribute	Type	Allowed Values	Default	Description
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S2\_S9

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 2-bit and 9-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

<sup>1</sup>WRITE\_MODE\_B=NO\_CHANGE.

<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.

<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S2_S9	8192 x 2	-	(12:0)	(1:0)	-	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIP A. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIP A) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

### Address Mapping

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the "Port Address Mapping for Data" table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in "Port Address Mapping for Parity" table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

### Port Address Mapping for Data

Data Width	Port Data Addresses																																				
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																			
4	4096	<--	7		6		5		4		3		2		1		0																				
8	2048	<--	3					2							1																						
16	1024	<--	1																																		
32	512	<--	0																																		

### Port Address Mapping for Parity

Parity Width	Port Parity Addresses													
1	2048	<-----	3				2				1			0
2	1024	<-----	1								0			
4	512	<-----	0											

#### Initializing Memory Contents of a Dual-Port RAMB16

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

#### Initializing the Output Register of a Dual-Port RAMB16

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The "Port A and Port B Conflict Resolution" section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

*WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE*

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/Hexidecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/Hexidecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.

Attribute	Type	Allowed Values	Default	Description
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S36

Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 36-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
512	32	512	4	(8:0)	(31:0)	(3:0)

The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL	SRVAL	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL	SRVAL	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change(a) RAM (addr)(b) data(c)	No Change(a) RAM (addr)(b) pdata(c)	RAM (addr)=>data	RAM (addr)=>pdata

GSR=Global Set Reset signal  
 INIT=Value specified by the INIT attribute for data memory. Default is all zeros.  
 SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
 (a) WRITE\_MODE=NO\_CHANGE  
 (b) WRITE\_MODE=READ\_FIRST  
 (c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# RAMB16\_S36\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with Two 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_A	INIT_A	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL_A	SRVAL_A	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL_A	SRVAL_A	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDRA	DIA	DIPA	DOA	DOPA	RAM Contents

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

<sup>1</sup>WRITE\_MODE\_B=NO\_CHANGE.

<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.

<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S36_S36	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the "Port Address Mapping for Data" table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in "Port Address Mapping for Parity" table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																			
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																		
4	4096	<--	7	6	5	4	3	2	1	0																										
8	2048	<--	3	2	1	0																														
16	1024	<--	1	0																																
32	512	<--	0																																	

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																		
1	2048	<----	3	2	1	0													
2	1024	<----	1	0															
4	512	<----	0																

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# RAMB16\_S4

Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 4-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
4096	4	-	-	(11:0)	(3:0)	-

The enable EN pin controls read, write, and reset for Port A. When EN is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When EN is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When EN is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when EN and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL	SRVAL	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL	SRVAL	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change(a) RAM (addr)(b) data(c)	No Change(a) RAM (addr)(b) pdata(c)	RAM (addr)=>data	RAM (addr)=>pdata

GSR=Global Set Reset signal  
 INIT=Value specified by the INIT attribute for data memory. Default is all zeros.  
 SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.  
 addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.  
 pdata=RAM parity data.  
 (a) WRITE\_MODE=NO\_CHANGE  
 (b) WRITE\_MODE=READ\_FIRST  
 (c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- RAMB16_S4: Virtex-II/II-Pro, Spartan-3/3E 4k x 4 Single-Port RAM
```

```
INIT_3D => X"0000000000000000000000000000000000000000000000000000000000000000",
INIT_3E => X"0000000000000000000000000000000000000000000000000000000000000000",
INIT_3F => X"0000000000000000000000000000000000000000000000000000000000000000"
port map (
DO => DO,      -- 4-bit Data Output

# RAMB16\_S4\_S18

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 18-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S4_S18	4096 x 4	-	(11:0)	(3:0)	-	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																		
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																	
4	4096	<--	7		6		5		4		3		2		1		0																		
8	2048	<--	3					2					1				0																		
16	1024	<--	1											0																					
32	512	<--	0																																

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																			
1	2048	<----	3					2						1																					0	
2	1024	<----	1											0																						
4	512	<----	0																																	

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

# RAMB16\_S4\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S4_S36	4096 x 4	-	(11:0)	(3:0)	-	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S4\_S4

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S4_S4	4096 x 4	-	(11:0)	(3:0)	-	4096 x 4	-	(11:0)	(3:0)	-

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																				
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																			
4	4096	<--	7			6			5			4			3			2			1			0													
8	2048	<--	3						2					1						0																	
16	1024	<--	1											0																							
32	512	<--	0																																		

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																					
1	2048	<----	3							2					1																						0	
2	1024	<----	1												0																							
4	512	<----	0																																			

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S4\_S9

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 4-bit and 9-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

<sup>1</sup>WRITE\_MODE\_B=NO\_CHANGE.

<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.

<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S4_S9	4096 x 4	-	(11:0)	(3:0)	-	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)

(a)Depth x Width

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIP A. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIP A) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																					
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																				
4	4096	<--	7			6			5			4			3			2			1			0														
8	2048	<--	3						2					1						0																		
16	1024	<--	1											0																								
32	512	<--	0																																			

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																					
1	2048	<-----	3							2						1																					0	
2	1024	<-----	1													0																						
4	512	<-----	0																																			

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S9

Primitive: 16K-bit Data and 2K-bit Parity Single-Port Synchronous Block RAM with 9-bit Port

## Introduction

This design element is a dedicated random access memory blocks with synchronous write capability. The block RAM port has 16384 bits of data memory. The cell configuration for this element is listed in the following table.

Data Cells		Parity Cells				
Depth	Width	Depth	Width	Address Bus	Data Bus	Parity Bus
2048	8	2048	1	(10:0)	(7:0)	(0:0)

The enable EN pin controls read, write, and reset for Port A. When EN is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When EN is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIP. When EN is High and WEA is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when EN and WEA are High, the data on the data inputs (DIA and DIP) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The above description assumes an active High EN, WE, SSR, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

## Logic Table

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT	INIT	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL	SRVAL	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL	SRVAL	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	EN	SSR	WE	CLK	ADDR	DI	DIP	DO	DOP	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change(a) RAM (addr)(b) data(c)	No Change(a) RAM (addr)(b) pdata(c)	RAM (addr)=>data	RAM (addr)=>pdata

GSR=Global Set Reset signal

INIT=Value specified by the INIT attribute for data memory. Default is all zeros.

SRVAL=Value after assertion of SSR as specified by the SRVAL attribute.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

(a) WRITE\_MODE=NO\_CHANGE

(b) WRITE\_MODE=READ\_FIRST

(c) WRITE\_MODE=WRITE\_FIRST

## Initialization

### Initializing Memory Contents

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16 is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

Any INIT\_xx or INITP\_xx attribute that is not specified is configured as zeros. Partial Strings are padded with zeros to the left.

### Initializing the Output Register

In Spartan-3A, each bit in the output register can be initialized at power on to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Two types of properties control initialization of the output register for a single-port RAMB16: INIT and SRVAL. The INIT attribute specifies the output register value at power on. You can use the SRVAL attribute to define the state resulting from assertion of the SSR (set/reset) input.

The INIT and SRVAL attributes specify the initialization value as a hexadecimal String containing one bit for each bit in the output port. For example, for a RAMB16\_S1 with port width equal to 1, the output register contains 1 bit. Therefore, the INIT or SRVAL value can only be specified as a 1 or 0. For RAMB16\_S4 with port width equal to 4, the output register contains 4 bits. In this case, you can specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT or SRVAL value.

### Selecting Write Mode

The WRITE\_MODE attribute controls RAMB16 memory and output contents. By default, the WRITE\_MODE is set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the WRITE\_MODE to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the WRITE\_MODE to NO\_CHANGE to have the input written to memory without changing the output.

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Binary/ Hexadecimal	Any Hex Value	All zeros	Identifies the initial value of the DO output port after completing configuration. The bit width is dependent on the width of the A or B port of the RAM.
INIT_00 - INIT_3F	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the data portion of the RAM array.
INITP_00 - INITP_07	Binary/ Hexadecimal	Any Hex Value	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SRVAL	Binary/ Hexadecimal	Any Hex Value	All zeros	Allows the individual selection of whether the DO output port sets (go to a one) or reset (go to a zero) upon the assertion of the SSR pin. The bit width is dependent on the width of the A or B port of the RAM.
WRITE_MODE	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DO port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;
```

```

# RAMB16\_S9\_S18

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit and 18-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR <sub>A</sub>	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT <sub>A</sub>	INIT <sub>A</sub>	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL <sub>A</sub>	SRVAL <sub>A</sub>	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL <sub>A</sub>	SRVAL <sub>A</sub>	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs

Truth Table B

Inputs								Outputs			
GSR	ENB	SSRB	WEB	CLKB	ADDRB	DIB	DIPB	DOB	DOPB	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_B	INIT_B	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL_B	SRVAL_B	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL_B	SRVAL_B	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change
0	1	0	1	↑	addr	data	pdata	No Change1, RAM(addr) =>data, data3	No Change1, RAM(addr) =>data, pdata3	RAM(addr) =>data	RAM(addr) =>pdata

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Component	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S9_S18	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)	1024 x 16	1024 x 2	(9:0)	(15:0)	(1:0)
(a) Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

The following tables show address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																	
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4	4096	<--	7	6	5	4	3	2	1	0																								
8	2048	<--	3	2	1	0																												
16	1024	<--	1	0																														
32	512	<--	0																															

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																	
1	2048	<-----	3	2	1	0												
2	1024	<-----	1	0														
4	512	<-----	0															

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S9\_S36

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit and 36-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_A	INIT_A	No Change	No Change

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

1WRITE\_MODE\_B=NO\_CHANGE.

2WRITE\_MODE\_B=READ\_FIRST.

3WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S9_S36	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)	512 x 32	512 x 4	(8:0)	(31:0)	(3:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPB. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the “Port Address Mapping for Data” table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in “Port Address Mapping for Parity” table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Widthport})) - 1$$

$$\text{End} = (\text{ADDRport}) * (\text{Widthport})$$

The following tables shows address mapping for each port width.

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																			
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
2	8192	<--	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																		
4	4096	<--	7	6	5	4	3	2	1	0																										
8	2048	<--	3	2	1	0																														
16	1024	<--	1	0																																
32	512	<--	0																																	

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																																		
1	2048	<-----	3	2	1	0																													
2	1024	<-----	1	0																															
4	512	<-----	0																																

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_ FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

# RAMB16\_S9\_S9

Primitive: 16K-bit Data and 2K-bit Parity Dual-Port Synchronous Block RAM with 9-bit Ports

## Introduction

This design element is a dual-ported dedicated random access memory block with synchronous write capability. Each block RAM port has 16384 bits of data memory. Ports configured as 9, 18, or 36-bits wide have an additional 2048 bits of parity memory. Each port is independent of the other while accessing the same set of 16384 data memory cells. Each port is independently configured to a specific data width. The possible port and cell configurations for this element are listed under "Port Descriptions."

## Logic Table

Truth Table A

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDR_A	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
1	X	X	X	X	X	X	X	INIT_A	INIT_A	No Change	No Change
0	0	X	X	X	X	X	X	No Change	No Change	No Change	No Change
0	1	1	0	↑	X	X	X	SRVAL_A	SRVAL_A	No Change	No Change
0	1	1	1	↑	addr	data	pdata	SRVAL_A	SRVAL_A	RAM(addr) =>data	RAM(addr) =>pdata
0	1	0	0	↑	addr	X	X	RAM(addr)	RAM(addr)	No Change	No Change

Inputs								Outputs			
GSR	ENA	SSRA	WEA	CLKA	ADDRA	DIA	DIPA	DOA	DOPA	RAM Contents	
										Data RAM	Parity RAM
0	1	0	1	↑	addr	data	pdata	No Change1, RAM(addr)2, data3	No Change1, RAM(addr)2, pdata3	RAM(addr) =>data	RAM(addr) =>pdata

GSR=Global Set Reset.

INIT\_B=Value specified by the INIT\_B attribute for output registers. Default is all zeros.

SRVAL\_B=register value.

addr=RAM address.

RAM(addr)=RAM contents at address ADDR.

data=RAM input data.

pdata=RAM parity data.

<sup>1</sup>WRITE\_MODE\_B=NO\_CHANGE.

<sup>2</sup>WRITE\_MODE\_B=READ\_FIRST.

<sup>3</sup>WRITE\_MODE\_B=WRITE\_FIRST.

## Port Descriptions

Port A						Port B				
Design Element	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus	Data Cells(a)	Parity Cells(a)	Address Bus	Data Bus	Parity Bus
RAMB16_S9_S9	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)	2048 x 8	2048 x 1	(10:0)	(7:0)	(0:0)
(a)Depth x Width										

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB. The enable ENA pin controls read, write, and reset for Port A. When ENA is Low, no data is written and the outputs (DOA and DOPA) retain the last state. When ENA is High and reset (SSRA) is High, DOA and DOPA are set to SRVAL\_A during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA and DIPA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_A=WRITE\_FIRST, when ENA and WEA are High, the data on the data inputs (DIA and DIPA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data outputs (DOA and DOPA) reflect the selected (addressed) word.

The enable ENB pin controls read, write, and reset for Port B. When ENB is Low, no data is written and the outputs (DOB and DOPB) retain the last state. When ENB is High and reset (SSRB) is High, DOB and DOPB are set to SRVAL\_B during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB and DIPB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. By default, WRITE\_MODE\_B=WRITE\_FIRST, when ENB and WEB are High, the data on the data inputs (DIB and PB) are loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data outputs (DOB and DOPB) reflect the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, SSRA, CLKA, ENB, WEB, SSRB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB16 port is absorbed into the block and does not use a CLB resource.

*Address Mapping*

Each port accesses the same set of 18432 memory cells using an addressing scheme that is dependent on the width of the port. For all port widths, 16384 memory cells are available for data as shown in the "Port Address Mapping for Data" table below. For 9-, 18-, and 36-bit wide ports, 2408 parity memory cells are also available as shown in "Port Address Mapping for Parity" table below. The physical RAM location that is addressed for a particular width is determined from the following formula.

$$\text{Start} = ((\text{ADDR port} + 1) * (\text{Width port})) - 1$$

$$\text{End} = (\text{ADDR port}) * (\text{Width port})$$

*Port Address Mapping for Data*

Data Width	Port Data Addresses																																	
1	16384	<--	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8	2048	<--	3	2	1	0																												
16	1024	<--	1	0																														
32	512	<--	0																															

*Port Address Mapping for Parity*

Parity Width	Port Parity Addresses																
1	2048	<----	3	2	1	0											
2	1024	<----	1	0													
4	512	<----	0														

*Initializing Memory Contents of a Dual-Port RAMB16*

You can use the INIT\_xx attributes to specify an initialization value for the memory contents of a RAMB16 during device configuration. The initialization of each RAMB16\_Sm\_Sn is set by 64 initialization attributes (INIT\_00 through INIT\_3F) of 64 hex values for a total of 16384 bits.

You can use the INITP\_xx attributes to specify an initial value for the parity memory during device configuration or assertion. The initialization of the parity memory for ports configured for 9, 18, or 36 bits is set by 8 initialization attributes (INITP\_00 through INITP\_07) of 64 hex values for a total of 2048 bits.

If any INIT\_xx or INITP\_xx attribute is not specified, it is configured as zeros. Partial Strings are padded with zeros to the left.

*Initializing the Output Register of a Dual-Port RAMB16*

In Spartan-3A, each bit in an output register can be initialized at power on (when GSR is high) to either a 0 or 1. In addition, the initial state specified for power on can be different than the state that results from assertion of a set/reset. Four properties control initialization of the output register for a dual-port RAMB16: INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B. The INIT\_A attribute specifies the output register value at power on for Port A and the INIT\_B attribute specifies the value for Port B. You can use the SRVAL\_A attribute to define the state resulting from assertion of the SSR (set/reset) input on Port A. You can use the SRVAL\_B attribute to define the state resulting from assertion of the SSR input on Port B.

The INIT\_A, INIT\_B, SRVAL\_A, and SRVAL\_B attributes specify the initialization value as a hexadecimal String. The value is dependent upon the port width. For example, for a RAMB16\_S1\_S4 with Port A width equal to 1 and Port B width equal to 4, the Port A output register contains 1 bit and the Port B output register contains 4 bits. Therefore, the INIT\_A or SRVAL\_A value can only be specified as a 1 or 0. For Port B, the output register contains 4 bits. In this case, you can use INIT\_B or SRVAL\_B to specify a hexadecimal value from 0 through F to initialize the 4 bits of the output register.

For those ports that include parity bits, the parity portion of the output register is specified in the high order bit position of the INIT\_A, INIT\_B, SRVAL\_A, or SRVAL\_B value.

The INIT and SRVAL attributes default to zero if they are not set by you.

#### Write Mode Selection

The WRITE\_MODE\_A attribute controls the memory and output contents of Port A for a dual-port RAMB16. The WRITE\_MODE\_B attribute does the same for Port B. By default, both WRITE\_MODE\_A and WRITE\_MODE\_B are set to WRITE\_FIRST. This means that input is read, written to memory, and then passed to output. You can set the write mode for Port A and Port B to READ\_FIRST to read the memory contents, pass the memory contents to the outputs, and then write the input to memory. Or, you can set the write mode to NO\_CHANGE to have the input written to memory without changing the output. The “Port A and Port B Conflict Resolution” section describes how read/write conflicts are resolved when both Port A and Port B are attempting to read/write to the same memory cells.

#### Port A and Port B Conflict Resolution

Spartan-3A block SelectRAM is True Dual-Port RAM that allows both ports to simultaneously access the same memory cell. When one port writes to a given memory cell, the other port must not address that memory cell (for a write or a read) within the clock-to-clock setup window.

The following tables summarize the collision detection behavior of the dual-port RAMB16 based on the WRITE\_MODE\_A and WRITE\_MODE\_B settings.

#### WRITE\_MODE\_A=NO\_CHANGE and WRITE\_MODE\_B=NO\_CHANGE

WEA	WEB	CLKA	CLKB	DIA	DIB	DIPA	DIPB	DOA	DOB	DOPA	DOPB	Data RAM	Parity Ram

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	Yes
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexadecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexadecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexadecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.

Attribute	Type	Allowed Values	Default	Description
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# RAMB4\_S1

Primitive: 4K-Bit Single-Port Synchronous Block RAM with Port Width Configured to 1 Bit

## Introduction

This design element is a dedicated, random access memory block with synchronous write capability. It provides the capability for fast, discrete, large blocks of RAM in each device. This element is configured as indicated in the following table:

Design Element	Depth	Width	Address Bus	Data Bus
RAMB4_S1	4096	1	(11:0)	(0:0)

The enable (EN) pin controls read, write, and reset. When EN is Low, no data is written and the output (DO) retains the last state. When EN is High and reset (RST) is High, DO is cleared during the Low-to-High clock (CLK) transition; if write enable (WE) is High, the memory contents reflect the data at DI. When EN is High and WE is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. When EN and WE are High, the data on the data input (DI) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data output (DO) reflects the selected (addressed) word. The above description assumes an active High EN, WE, RST, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This element can be initialized during configuration. Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

## Logic Table

Inputs						Outputs	
EN	RST	WE	CLK	ADDR	DI	DO	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address.  
RAM(addr)=RAM contents at address ADDR.  
data=RAM input data.

### Specifying Initial Contents of a Block RAM -

You can use the INIT\_xx attributes to specify an initial value during device configuration. The initialization of each of these elements is set by 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

# RAMB4\_S1\_S1

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S1_S1	4096	1	(11:0)	(0:0)	4096	1	(11:0)	(0:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR[A]) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR[A]) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR[B]) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR[B]) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
RAM(addr)=RAM contents at address ADDRA/ADDRB  
data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																	
1	4096	<-----	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S1\_S16

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 16-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S1_S16	4096	1	(11:0)	(0:0)	256	16	(7:0)	(15:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR B) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR B) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_ *architecture* symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs

# RAMB4\_S1\_S2

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 2-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S1_S2	4096	1	(11:0)	(0:0)	2048	2	(10:0)	(1:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR[A]) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR[A]) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR[B]) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR[B]) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
RAM(addr)=RAM contents at address ADDR A/ADDR B  
data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																	
1	4096	<-----	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
2	2048	<-----	7		6		5		4		3		2		1		0	

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT_00 To INIT_3F	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the data portion of the RAM array.
INIT_A	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INIT_B	Binary/ Hexidecimal	Any	All zeros	Identifies the initial value of the DOA/DOB output port after completing configuration. For Type, the bit width is dependent on the width of the A or B port of the RAM.
INITP_00 To INITP_07	Binary/ Hexidecimal	Any	All zeros	Specifies the initial contents of the parity portion of the RAM array.
SIM_COLLISION_CHECK	String	"ALL", "NONE", "WARNING", or "GENERATE_X_ONLY"	"ALL"	Specifies the behavior during simulation in the event of a data collision (data being read or written to the same address from both ports of the Ram simultaneously. "ALL" issues a warning to simulator console and generate an X or all unknown data due to the collision. This is the recommended setting. "WARNING" generates a warning only and "GENERATE_X_ONLY" generates an X for unknown data but won't output the occurrence to the simulation console. "NONE" completely ignores the error. It is suggested to only change this attribute if you can ensure the data generated during a collision is discarded.
SRVAL_A	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTA pin. For Type, the bit width is dependent on the width of the A port of the RAM.
SRVAL_B	Binary/ Hexidecimal	Any	All zeros	Allows the individual selection of whether the DOA/DOB output port sets (go to a one) or reset (go to a zero) upon the assertion of the RSTB pin. For Type, the bit width is dependent on the width of the B port of the RAM.
WRITE_MODE_A	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM
WRITE_MODE_B	String	"WRITE_FIRST", "READ_FIRST" or "NO_CHANGE"	"WRITE_FIRST"	Specifies the behavior of the DOA/DOB port upon a write command to the respected port. If set to "WRITE_FIRST", the same port that is written to displays the contents of the written data to the outputs upon completion of the operation. "READ_FIRST" displays the prior contents of the RAM to the output port prior to writing the new data. "NO_CHANGE" keeps the previous value on the output port and won't update the

Attribute	Type	Allowed Values	Default	Description
				output port upon a write command. This is the suggested mode if not using the read data from a particular port of the RAM.

## RAMB4\_S1\_S4

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 4-bits

### Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S1_S4	4096	1	(11:0)	(0:0)	1024	4	(9:0)	(3:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR[A]) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR[A]) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR[B]) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR[B]) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents

1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDRA/ADDRB  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																	
1	4096	<-----	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	1024	<-----	3				2				1				0			

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

## RAMB4\_S1\_S8

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 1-bit and 8-bits

### Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S1_S8	4096	1	(11:0)	(0:0)	512	8	(8:0)	(7:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR[A]) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR[A]) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR[B]) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR[B]) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word. The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDRA/ADDRB  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																	
1	4096	<-----	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8	512	<-----	1								0							

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S16

Primitive: 4096-Bit Single-Port Synchronous Block RAM with Port Width Configured to 16 Bits

## Introduction

This design element is a dedicated, random access memory block with synchronous write capability. It provides the capability for fast, discrete, large blocks of RAM in each device. This element is configured as indicated in the following table:

Design Element	Depth	Width	Address Bus	Data Bus
RAMB4_S16	256	16	(7:0)	(15:0)

The enable (EN) pin controls read, write, and reset. When EN is Low, no data is written and the output (DO) retains the last state. When EN is High and reset (RST) is High, DO is cleared during the Low-to-High clock (CLK) transition; if write enable (WE) is High, the memory contents reflect the data at DI. When EN is High and WE is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. When EN and WE are High, the data on the data input (DI) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data output (DO) reflects the selected (addressed) word. The above description assumes an active High EN, WE, RST, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This element can be initialized during configuration. Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_ *architecture* symbol.

## Logic Table

Inputs						Outputs	
EN	RST	WE	CLK	ADDR	DI	DO	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address.  
RAM(addr)=RAM contents at address ADDR.  
data=RAM input data.

### Specifying Initial Contents of a Block RAM -

You can use the INIT\_xx attributes to specify an initial value during device configuration. The initialization of each of these elements is set by 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

# RAMB4\_S16\_S16

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 16-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S16_S16	256	16	(7:0)	(15:0)	256	16	(7:0)	(15:0)
ADDR=address bus for the port								
DI=data input bus for the port								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR B) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR B) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
RAM(addr)=RAM contents at address ADDRA/ADDRB  
data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses
16	256 <----- 0

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S2

Primitive: 4K-bit Single-Port Synchronous Block RAM with Port Width Configured to 2-bits

## Introduction

This design element is a dedicated, random access memory block with synchronous write capability. It provides the capability for fast, discrete, large blocks of RAM in each device. This element is configured as indicated in the following table:

Design Element	Depth	Width	Address Bus	Data Bus
RAMB4_S2	2048	2	(10:0)	(1:0)

The enable (EN) pin controls read, write, and reset. When EN is Low, no data is written and the output (DO) retains the last state. When EN is High and reset (RST) is High, DO is cleared during the Low-to-High clock (CLK) transition; if write enable (WE) is High, the memory contents reflect the data at DI. When EN is High and WE is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. When EN and WE are High, the data on the data input (DI) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data output (DO) reflects the selected (addressed) word. The above description assumes an active High EN, WE, RST, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This element can be initialized during configuration. Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

## Logic Table

Inputs						Outputs	
EN	RST	WE	CLK	ADDR	DI	DO	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.

### Specifying Initial Contents of a Block RAM -

You can use the INIT\_xx attributes to specify an initial value during device configuration. The initialization of each of these elements is set by 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## RAMB4\_S2\_S16

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 16-bits

### Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S2_S16	2048	2	(10:0)	(1:0)	256	16	(7:0)	(15:0)
ADDR=address bus for the port.								
DI=data input bus for the port.								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR\_A) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR\_A) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR\_B) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR\_B) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the `INIT_0x` attributes to specify an initial value during device configuration. There are 16 initialization attributes (`INIT_00` through `INIT_0F`) of 64 hex values for a total of 4096 bits. If any `INIT_0x` attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change

1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDRA/ADDRB  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																
2	2048	<-----	7		6		5		4		3		2		1		0
16	256	<-----	0														

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S2\_S2

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 2-bits

## Introduction

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S2_S2	2048	2	(10:0)	(1:0)	2048	2	(10:0)	(1:0)
ADDR=address bus for the port								
DI=data input bus for the port								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR B) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR B) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate *STARTUP\_architecture* symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

- See the [Virtex-II Data Sheets](#).

# RAMB4\_S2\_S4

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 4-bits

## Introduction

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S2_S4	2048	2	(10:0)	(1:0)	1024	4	(9:0)	(3:0)
ADDR=address bus for the port.								
DI=data input bus for the port.								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This component can be initialized during configuration. See the logic table below.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_ *architecture* symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDRA/ADDRB  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																
2	2048	<-----	7		6		5		4		3		2		1		0
4	1024	<-----	3				2				1				0		

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# RAMB4\_S2\_S8

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 2-bits and 8-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S2_S8	2048	2	(10:0)	(1:0)	512	8	(8:0)	(7:0)
ADDR=address bus for the port.								
DI=data input bus for the port.								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR A) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR A) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR B) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR B) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Width\ port)) - 1$
- $End = (ADDR\ port) * (Width\ port)$

Port Width	Port Addresses																
2	2048	<-----	7		6		5		4		3		2		1		0
8	512	<-----	1								0						

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S4

Primitive: 4k-bit Single-Port Synchronous Block RAM with Port Width Configured to 4-bits

## Introduction

This design element is a dedicated, random access memory block with synchronous write capability. It provides the capability for fast, discrete, large blocks of RAM in each device. This element is configured as indicated in the following table:

Design Element	Depth	Width	Address Bus	Data Bus
RAMB4_S4	1024	4	(9:0)	(3:0)

The enable (EN) pin controls read, write, and reset. When EN is Low, no data is written and the output (DO) retains the last state. When EN is High and reset (RST) is High, DO is cleared during the Low-to-High clock (CLK) transition; if write enable (WE) is High, the memory contents reflect the data at DI. When EN is High and WE is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. When EN and WE are High, the data on the data input (DI) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data output (DO) reflects the selected (addressed) word. The above description assumes an active High EN, WE, RST, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This element can be initialized during configuration. Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

## Logic Table

Inputs						Outputs	
EN	RST	WE	CLK	ADDR	DI	DO	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address.  
 RAM(addr)=RAM contents at address ADDR.  
 data=RAM input data.

### Specifying Initial Contents of a Block RAM -

You can use the INIT\_xx attributes to specify an initial value during device configuration. The initialization of each of these elements is set by 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

```

# RAMB4\_S4\_S16

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 16-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S4_S16	1024	4	(9:0)	(3:0)	256	16	(7:0)	(15:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the `INIT_0x` attributes to specify an initial value during device configuration. There are 16 initialization attributes (`INIT_00` through `INIT_0F`) of 64 hex values for a total of 4096 bits. If any `INIT_0x` attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDRA/ADDRB  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR\ port + 1) * (Widthport)) - 1$
- $End = (ADDRport) * (Widthport)$

Port Width	Port Addresses															
4	1024	<-----	3				2				1				0	
16	256	<-----	0													

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S4\_S4

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 4-bits

## Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S4_S4	1024	4	(9:0)	(3:0)	1024	4	(9:0)	(3:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the `INIT_0x` attributes to specify an initial value during device configuration. There are 16 initialization attributes (`INIT_00` through `INIT_0F`) of 64 hex values for a total of 4096 bits. If any `INIT_0x` attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
RAM(addr)=RAM contents at address ADDR<sub>A</sub>/ADDR<sub>B</sub>  
data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR_{port} + 1) * (Width_{port})) - 1$
- $End = (ADDR_{port}) * (Width_{port})$

Port Width	Port Addresses															
4	1024	<-----	3				2				1				0	

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

# RAMB4\_S4\_S8

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 4-bits and 8-bits

## Introduction

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S4_S8	1024	4	(9:0)	(3:0)	512	8	(8:0)	(7:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRA) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDRA) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_ *architecture* symbol.

You can use the INIT\_0x attributes to specify an initial value during device configuration. There are 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

# RAMB4\_S8

Primitive: 4k-bit Single-Port Synchronous Block RAM with Port Width Configured to 8-bits

## Introduction

This design element is a dedicated, random access memory block with synchronous write capability. It provides the capability for fast, discrete, large blocks of RAM in each device. This element is configured as indicated in the following table:

Design Element	Depth	Width	Address Bus	Data Bus
RAMB4_S8	512	8	(8:0)	(7:0)

The enable (EN) pin controls read, write, and reset. When EN is Low, no data is written and the output (DO) retains the last state. When EN is High and reset (RST) is High, DO is cleared during the Low-to-High clock (CLK) transition; if write enable (WE) is High, the memory contents reflect the data at DI. When EN is High and WE is Low, the data stored in the RAM address (ADDR) is read during the Low-to-High clock transition. When EN and WE are High, the data on the data input (DI) is loaded into the word selected by the write address (ADDR) during the Low-to-High clock transition and the data output (DO) reflects the selected (addressed) word. The above description assumes an active High EN, WE, RST, and CLK. However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

This element can be initialized during configuration. Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate STARTUP\_architecture symbol.

## Logic Table

Inputs						Outputs	
EN	RST	WE	CLK	ADDR	DI	DO	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address.  
RAM(addr)=RAM contents at address ADDR.  
data=RAM input data.

### Specifying Initial Contents of a Block RAM -

You can use the INIT\_xx attributes to specify an initial value during device configuration. The initialization of each of these elements is set by 16 initialization attributes (INIT\_00 through INIT\_0F) of 64 hex values for a total of 4096 bits. If any INIT\_0x attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## RAMB4\_S8\_S16

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 8-bits and 16-bits

### Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S8_S16	512	8	(8:0)	(7:0)	256	16	(7:0)	(15:0)
ADDR=address bus for the port.								
DI=data input bus for the port.								

All Port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All Port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDR[A]) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDR[A]) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDR[B]) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDR[B]) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the `INIT_0x` attributes to specify an initial value during device configuration. There are 16 initialization attributes (`INIT_00` through `INIT_0F`) of 64 hex values for a total of 4096 bits. If any `INIT_0x` attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDR<sub>A</sub>/ADDR<sub>B</sub>  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR_{port} + 1) * (Width_{port})) - 1$
- $End = (ADDR_{port}) * (Width_{port})$

Port Width	Port Addresses																
8	512	<-----	1														0
16	256	<-----	0														

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

## RAMB4\_S8\_S8

Primitive: 4K-bit Dual-Port Synchronous Block RAM with Port Widths Configured to 8-bits

### Introduction

This design element is a 4096-bit dual-ported dedicated random access memory block with synchronous write capability. Each port is independent of the other while accessing the same set of 4096 memory cells. Each port is independently configured to a specific data width, as expressed in the following table:

Design Element	Port A Depth	Port A Width	Port A ADDR	Port A DI	Port B Depth	Port B Width	Port B ADDR	Port B DI
RAMB4_S8_S8	512	8	(8:0)	(7:0)	512	8	(8:0)	(7:0)
ADDR=address bus for the port								
DI=data input bus for the port								

Each port is fully synchronous with independent clock pins. All port A input pins have setup time referenced to the CLKA pin and its data output bus DOA has a clock-to-out time referenced to the CLKA. All port B input pins have setup time referenced to the CLKB pin and its data output bus DOB has a clock-to-out time referenced to the CLKB.

The enable ENA pin controls read, write, and reset for port A. When ENA is Low, no data is written and the output (DOA) retains the last state. When ENA is High and reset (RSTA) is High, DOA is cleared during the Low-to-High clock (CLKA) transition; if write enable (WEA) is High, the memory contents reflect the data at DIA. When ENA is High and WEA is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENA and WEA are High, the data on the data input (DIA) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOA) reflects the selected (addressed) word.

The enable ENB pin controls read, write, and reset for port B. When ENB is Low, no data is written and the output (DOB) retains the last state. When ENB is High and reset (RSTB) is High, DOB is cleared during the Low-to-High clock (CLKB) transition; if write enable (WEB) is High, the memory contents reflect the data at DIB. When ENB is High and WEB is Low, the data stored in the RAM address (ADDRB) is read during the Low-to-High clock transition. When ENB and WEB are High, the data on the data input (DIB) is loaded into the word selected by the write address (ADDRB) during the Low-to-High clock transition and the data output (DOB) reflects the selected (addressed) word.

The above descriptions assume active High control pins (ENA, WEA, RSTA, CLKA, ENB, WEB, RSTB, and CLKB). However, the active level can be changed by placing an inverter on the port. Any inverter placed on a RAMB4 port is absorbed into the block and does not use a CLB resource.

Block RAM output registers are asynchronously cleared, output Low, when power is applied. The initial contents of the block RAM are not altered. For FPGA devices, power-on conditions are simulated when global set/reset (GSR) is active. GSR defaults to active-High but can be inverted by adding an inverter in front of the GSR input of the appropriate `STARTUP_architecture` symbol.

You can use the `INIT_0x` attributes to specify an initial value during device configuration. There are 16 initialization attributes (`INIT_00` through `INIT_0F`) of 64 hex values for a total of 4096 bits. If any `INIT_0x` attribute is not specified, it is configured as zeros. Partial initialization strings are padded with zeros to the left.

## Logic Table

Inputs						Outputs	
EN(A/B)	RST(A/B)	WE(A/B)	CLK(A/B)	ADDR(A/B)	DI(A/B)	DO(A/B)	RAM Contents
0	X	X	X	X	X	No Change	No Change
1	1	0	↑	X	X	0	No Change
1	1	1	↑	addr	data	0	RAM(addr) =>data
1	0	0	↑	addr	X	RAM(addr)	No Change
1	0	1	↑	addr	data	data	RAM(addr) =>data

addr=RAM address of port A/B  
 RAM(addr)=RAM contents at address ADDR<sub>A</sub>/ADDR<sub>B</sub>  
 data=RAM input data at pins DIA/DIB

## Port Descriptions

**Address Mapping** - Each port accesses the same set of 4096 memory cells using an addressing scheme that is dependent on the width of the port. The physical RAM location that is addressed for a particular width is determined from the following formula.

- $Start = ((ADDR_{port} + 1) * (Width_{port})) - 1$
- $End = (ADDR_{port}) * (Width_{port})$

Port Width	Port Addresses														
8	512	<-----	1								0				

**Port Conflict resolution** - This design element is a true dual-ported RAM in that it allows simultaneous reads of the same memory cell. When one port is performing a write to a given memory cell, the other port should not address that memory cell (for a write or a read) within the clock-to-clock setup window.

- If both ports write to the same memory cell simultaneously, violating the clock-to-setup requirement, the data stored will be invalid.
- If one port attempts to read from the same memory cell that the other is simultaneously writing to, violating the clock setup requirement, the write will be successful but the data read will be invalid.

## Design Entry Method

Instantiation	Recommended
Inference	No

Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

# ROM128X1

Primitive: 128-Deep by 1-Wide ROM

## Introduction

This design element is a 128-word by 1-bit read-only memory. The data output (O) reflects the word selected by the 7-bit address (A6 – A0). The ROM is initialized to a known value during configuration with the INIT=value parameter. The value consists of 32 hexadecimal digits that are written into the ROM from the most-significant digit A=FH to the least-significant digit A=0H. An error occurs if the INIT=value is not specified.

## Logic Table

Input				Output
I0	I1	I2	I3	O
0	0	0	0	INIT(0)
0	0	0	1	INIT(1)
0	0	1	0	INIT(2)
0	0	1	1	INIT(3)
0	1	0	0	INIT(4)

# ROM16X1

Primitive: 16-Deep by 1-Wide ROM

## Introduction

This design element is a 16-word by 1-bit read-only memory. The data output (O) reflects the word selected by the 4-bit address (A3 – A0). The ROM is initialized to a known value during configuration with the INIT=value parameter. The value consists of four hexadecimal digits that are written into the ROM from the most-significant digit A=FH to the least-significant digit A=0H. For example, the INIT=10A7 parameter produces the data stream: 0001 0000 1010 0111. An error occurs if the INIT=value is not specified.

## Logic Table

# ROM32X1

Primitive: 32-Deep by 1-Wide ROM

## Introduction

This design element is a 32-word by 1-bit read-only memory. The data output (O) reflects the word selected by the 5-bit address (A4 – A0). The ROM is initialized to a known value during configuration with the INIT=value parameter. The value consists of eight hexadecimal digits that are written into the ROM from the most-significant digit A=1FH to the least-significant digit A=00H.

For example, the INIT=10A78F39 parameter produces the data stream: 0001 0000 1010 0111 1000 1111 0011 1001. An error occurs if the INIT=value is not specified.

# SRL16

Primitive: 16-Bit Shift Register Look-Up-Table (LUT)

## Introduction

This design element is a shift register look-up table (LUT). The inputs A3, A2, A1, and A0 select the output length of the shift register.

The shift register can be of a fixed, static length or it can be dynamically adjusted.

- **To create a fixed-length shift register** - Drive the A3 through A0 inputs with static values. The length of the shift register can vary from 1 bit to 16 bits, as determined by the following formula:  $\text{Length} = (8 \times A3) + (4 \times A2) + (2 \times A1) + A0 + 1$ . If A3, A2, A1, and A0 are all zeros (0000), the shift register is one bit long. If they are all ones (1111), it is 16 bits long.
- **To change the length of the shift register dynamically** - Change the values driving the A3 through A0 inputs. For example, if A2, A1, and A0 are all ones (111) and A3 toggles between a one (1) and a zero (0), the length of the shift register changes from 16 bits to 8 bits. Internally, the length of the shift register is always 16 bits and the input lines A3 through A0 select which of the 16 bits reach the output.

The shift register LUT contents are initialized by assigning a four-digit hexadecimal number to an INIT attribute. The first, or the left-most, hexadecimal digit is the most significant bit. If an INIT value is not specified, it defaults to a value of four zeros (0000) so that the shift register LUT is cleared during configuration.

The data (D) is loaded into the first bit of the shift register during the Low-to-High clock (CLK) transition. During subsequent Low-to-High clock transitions data shifts to the next highest bit position while new data is loaded. The data appears on the Q output when the shift register length determined by the address inputs is reached.

## Logic Table

Inputs			Output
A <sub>m</sub>	CLK	D	Q
A <sub>m</sub>	X	X	Q(A <sub>m</sub> )
A <sub>m</sub>	↑	D	Q(A <sub>m</sub> - 1)
m = 0, 1, 2, 3			

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 16-Bit Value	All zeros	Sets the initial value of Q output after configuration.

# SRLC16\_1

Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry and Negative-Edge Clock

## Introduction

This design element is a shift register look-up table (LUT) with carry and a negative-edge clock. The inputs A3, A2, A1, and A0 select the output length of the shift register.

The shift register can be of a fixed, static length or it can be dynamically adjusted.

- To create a fixed-length shift register** - Drive the A3 through A0 inputs with static values. The length of the shift register can vary from 1 bit to 16 bits, as determined by the following formula:  $\text{Length} = (8 \times A3) + (4 \times A2) + (2 \times A1) + A0 + 1$ . If A3, A2, A1, and A0 are all zeros (0000), the shift register is one bit long. If they are all ones (1111), it is 16 bits long.
- To change the length of the shift register dynamically** - Change the values driving the A3 through A0 inputs. For example, if A2, A1, and A0 are all ones (111) and A3 toggles between a one (1) and a zero (0), the length of the shift register changes from 16 bits to 8 bits. Internally, the length of the shift register is always 16 bits and the input lines A3 through A0 select which of the 16 bits reach the output.

The shift register LUT contents are initialized by assigning a four-digit hexadecimal number to an INIT attribute. The first, or the left-most, hexadecimal digit is the most significant bit. If an INIT value is not specified, it defaults to a value of four zeros (0000) so that the shift register LUT is cleared during configuration.

The Q15 output is available for your use in cascading multiple shift register LUTs to create larger shift registers.

## Logic Table

Inputs			Output	
A <sub>m</sub>	CLK	D	Q	Q15
A <sub>m</sub>	X	X	Q(A <sub>m</sub> )	No Change
A <sub>m</sub>	↓	D	Q(A <sub>m</sub> - 1)	Q14
m = 0, 1, 2, 3

# SRLC16E

Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry and Clock Enable

## Introduction

This design element is a shift register look-up table (LUT) with carry and clock enable. The inputs A3, A2, A1, and A0 select the output length of the shift register.

The shift register can be of a fixed, static length or it can be dynamically adjusted.

- **To create a fixed-length shift register** - Drive the A3 through A0 inputs with static values. The length of the shift register can vary from 1 bit to 16 bits, as determined by the following formula:  $\text{Length} = (8 \times A3) + (4 \times A2) + (2 \times A1) + A0 + 1$ . If A3, A2, A1, and A0 are all zeros (0000), the shift register is one bit long. If they are all ones (1111), it is 16 bits long.
- **To change the length of the shift register dynamically** - Change the values driving the A3 through A0 inputs. For example, if A2, A1, and A0 are all ones (111) and A3 toggles between a one (1) and a zero (0), the length of the shift register changes from 16 bits to 8 bits. Internally, the length of the shift register is always 16 bits and the input lines A3 through A0 select which of the 16 bits reach the output.

The shift register LUT contents are initialized by assigning a four-digit hexadecimal number to an INIT attribute. The first, or the left-most, hexadecimal digit is the most significant bit. If an INIT value is not specified, it defaults to a value of four zeros (0000) so that the shift register LUT is cleared during configuration.

The data (D) is loaded into the first bit of the shift register during the Low-to-High clock (CLK) transition. When CE is High, during subsequent Low-to-High clock transitions, data shifts to the next highest bit position as new data is loaded. The data appears on the Q output when the shift register length determined by the address inputs is reached.

The Q15 output is available for you in cascading to multiple shift register LUTs to create larger shift registers.

## Logic Table

Inputs				Output	
Am	CLK	CE	D	Q	Q15
Am	X	0	X	Q(Am)	Q(15)
Am	X	1	X	Q(Am)	Q(15)
Am	↑	1	D	Q(Am - 1)	Q15

m= 0, 1, 2, 3

## Design Entry Method

Instantiation	Yes
Inference	Recommended

---

Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 16-Bit Value	All zeros	Sets the initial value of content and output of shift register after configuration.

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- SRLC16E: 16-bit cascable shift register LUT with clock enable operating on posedge of clock
--           Virtex-II/II-Pro, Spartan-3/3E/3A
-- Xilinx HDL Libraries Guide, version 10.1.2

SRLC16E_inst : SRLC16E
generic map (
  INIT => X"0000")
port map (
  Q => Q,          -- SRL data output
  Q15 => Q15,     -- Carry output (connect to next SRL)

# SRLC16E\_1

Primitive: 16-Bit Shift Register Look-Up Table (LUT) with Carry, Negative-Edge Clock, and Clock Enable

## Introduction

This design element is a shift register look-up table (LUT) with carry, clock enable, and negative-edge clock. The inputs A3, A2, A1, and A0 select the output length of the shift register.

The shift register can be of a fixed, static length or it can be dynamically adjusted.

- **To create a fixed-length shift register** - Drive the A3 through A0 inputs with static values. The length of the shift register can vary from 1 bit to 16 bits, as determined by the following formula:  $\text{Length} = (8 \times A3) + (4 \times A2) + (2 \times A1) + A0 + 1$ . If A3, A2, A1, and A0 are all zeros (0000), the shift register is one bit long. If they are all ones (1111), it is 16 bits long.
- **To change the length of the shift register dynamically** - Change the values driving the A3 through A0 inputs. For example, if A2, A1, and A0 are all ones (111) and A3 toggles between a one (1) and a zero (0), the length of the shift register changes from 16 bits to 8 bits. Internally, the length of the shift register is always 16 bits and the input lines A3 through A0 select which of the 16 bits reach the output.

The shift register LUT contents are initialized by assigning a four-digit hexadecimal number to an INIT attribute. The first, or the left-most, hexadecimal digit is the most significant bit. If an INIT value is not specified, it defaults to a value of four zeros (0000) so that the shift register LUT is cleared during configuration.

When CE is High, the data (D) is loaded into the first bit of the shift register during the High-to-Low clock (CLK) transition. During subsequent High-to-Low clock transitions data shifts to the next highest bit position as new data is loaded when CE is High. The data appears on the Q output when the shift register length determined by the address inputs is reached.

The Q15 output is available for your use in cascading multiple shift register LUTs to create larger shift registers.

## Logic Table

Inputs				Output	
Am	CE	CLK	D	Q	Q15
Am	0	X	X	Q(Am)	No Change
Am	1	X	X	Q(Am)	No Change
Am	1	↓	D	Q(Am - 1 )	Q14
m= 0, 1, 2, 3					

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## Available Attributes

Attribute	Type	Allowed Values	Default	Description
INIT	Hexadecimal	Any 16-Bit Value	All zeros	Sets the initial value of content and output of shift register after configuration.

# STARTUP\_VIRTEX2

Primitive: Virtex-II, Virtex-II Pro, and Virtex-II User Interface to Global Clock, Reset, and 3-State Controls

## Introduction

This design element is used for Global Set/Reset, global 3-state control, and the user configuration clock. The Global Set/Reset (GSR) input, when High, sets or resets all flip-flops, all latches, and every block RAMB16 output register in the device, depending on the initialization state (INIT=1 or 0) of the component. For Virtex and Virtex-E, see “STARTUP\_VIRTEX”.

**Note** Block RAM content, LUT RAMs, the Digital Clock Manager (DCM), and shift register LUTs (SRL16, SRL16\_1, SRL16E, SRL16E\_1, SRLC16, SRLC16\_1, SRLC16E, and SRLC16E\_1) are not set/reset.

Following configuration, the global 3-state control (GTS), when High—and BSCAN is not enabled and executing an EXTEST instruction—forces all the IOB outputs into high impedance mode, which isolates the device outputs from the circuit but leaves the inputs active.

**Note** GTS= Global 3-State

Including the STARTUP\_VIRTEX2 symbol in a design is optional. You must include the symbol under the following conditions.

- To exert external control over global set/reset, connect the GSR pin to a top level port and an IBUF.
- To exert external control over global 3-state, connect the GTS pin to a top level port and IBUF.
- To synchronize startup to a user clock, connect the user clock signal to the CLK input. Furthermore, “user clock” must be selected in the BitGen program.

You can use location constraints to specify the pin from which GSR or GTS (or both) is accessed.

## Design Entry Method

Instantiation	Recommended
Inference	No
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```
Library UNISIM;
use UNISIM.vcomponents.all;

-- STARTUP_VIRTEX2: Startup primitive for GSR, GTS or startup sequence
--                   control. Virtex-II/II-Pro
-- Xilinx HDL Libraries Guide, version 10.1.2

STARTUP_VIRTEX2_inst : STARTUP_VIRTEX2
port map (
CLK => CLK,          -- Clock input for start-up sequence
GSR => GSR_PORT,    -- Global Set/Reset input (GSR cannot be used for the port name)
```

```
GTS => GTS_PORT -- Global 3-state input (GTS cannot be used for the port name)
);
-- End of STARTUP_VIRTEX2_inst instantiation
```

## Verilog Instantiation Template

```
// STARTUP_VIRTEX2: Startup primitive for GSR, GTS or startup sequence
// control. Virtex-II/II-Pro
// Xilinx HDL Libraries Guide, version 10.1.2

STARTUP_VIRTEX2 STARTUP_VIRTEX2_inst (
.CLK(CLK), // Clock input for start-up sequence
.GSR(GSR_PORT), // Global Set/Reset input (GSR can not be used as a port name)
.GTS(GTS_PORT) // Global 3-state input (GTS can not be used as a port name)
);

// End of STARTUP_VIRTEX2_inst instantiation
```

# XORCY

Primitive: XOR for Carry Logic with General Output

## Introduction

This design element is a special XOR with general O output that generates faster and smaller arithmetic functions. The XORCY primitive is a dedicated XOR function within the carry-chain logic of the slice. It allows for fast and efficient creation of arithmetic (add/subtract) or wide logic functions (large AND/OR gate).

## Logic Table

Input		Output
LI	CI	O
0	0	0
0	1	1
1	0	1
1	1	0

## Design Entry Method

Instantiation	Yes
Inference	Recommended
Coregen and wizards	No
Macro support	No

## VHDL Instantiation Template

Unless they already exist, copy the following two statements and paste them before the entity declaration.

```

Library UNISIM;
use UNISIM.vcomponents.all;

-- XORCY: Carry-Chain XOR-gate with general output
-- Xilinx HDL Libraries Guide, version 10.1.2

XORCY_inst : XORCY
port map (
O => O, -- XOR output signal
CI => CI, -- Carry input signal
LI => LI -- LUT4 input signal
);

-- End of XORCY_inst instantiation
    
```

## Verilog Instantiation Template

```
// XORCY: Carry-Chain XOR-gate with general output
//           For use with All FPGAs
// Xilinx HDL Libraries Guide, version 10.1.2

XORCY XORCY_inst (
.O(O), // XOR output signal
.CI(CI), // Carry input signal
.LI(LI) // LUT4 input signal
);

// End of XORCY_inst instantiation
```
