# The Reliability Program

---

## Overview

Xilinx publishes this report to provide customers with insight regarding the reliability of Xilinx<sup>®</sup> products. Reliability is defined as product performance to specification over time in response to varied (specified) environmental stress conditions. The goal of the reliability program is to achieve continuous improvement in the robustness of each product being evaluated.

As part of this program, finished product reliability is measured periodically to ensure that the product performance meets or exceeds reliability specifications. Reliability programs are executed in response to internal programs.

The reliability qualifications of new devices, wafer processes, and packages are designed to ensure that Xilinx products satisfy internal requirements before transfer into production. The reliability qualification and monitoring requirements are outlined in [Table 1-1](#) through [Table 1-18](#). The reliability stress tests are conducted according to the conditions specified in JEDEC Solid State Technology Association's reliability test methods for packaged devices, JESD22, except Group B and D tests in which it follows DSCC test methods, MIL-STD-883.

**Note:** In this report, *obsolete* refers to Xilinx products for which a Product Discontinuation Notice (PDN) has been issued to cease the shipment and to data more than two years old that is no longer valid due to a process change.

## Product Qualification

The reliability tests used for wafer process qualification are summarized in [Table 1-1](#).

**Table 1-1: Wafer Process Qualification Tests**

1. FIT is *failure in time*. Phase I production is released as the qualification data demonstrates, meeting the required 200 FIT failure rate and other test requirements.
2. Phase II production is released as the qualification data demonstrates, meeting the required 50 FIT failure rate and other test requirements.
3. Package preconditioning is performed prior to THB, HAST, temperature cycling, TH, and HASTU tests.
4. For plastic QFP packages: -65°C to +150°C and 500 cycles or -55°C to +125°C and 1,000 cycles.
5. For plastic BGA packages: -55°C to +125°C and 1,000 cycles.

7. For CPLD and EPROM products.
8. This is not a mandatory test and only for CPLD and EPROM products.

## Non-Hermetic and Hermetic Packages

Moisture sensitivity and reflow temperature information can be found in *Device Package User Guide* (UG112) [\[Ref 1\]](#).

The non-hermetic package/assembly qualification is outlined in [Table 1-2](#). However, for hermetic package qualification, a full group B and D test per MIL-STD-883C, *Test Methods*, is required.

**Table 1-2: Non-Hermetic Package/Assembly Qualification**

The qualification process for new devices is shown in [Table 1-3](#).

**Table 1-3: Device Qualification**

Reliability Test	Conditions	Lot Quantity	Sample Size per Lot	Target Criteria

**Notes:**

1. HBM = Human Body Model.
2. CDM = Charge Device Model.
3. GT transceiver CDM level is specified per JEP157.

## Reliability Monitor Program

The wafer process reliability monitor program is based on the maturity of the wafer process, the number of device hours, and the failure in time (FIT) rate. All processes are divided into one of two classes to determine how often the process is monitored annually. Class 1 processes are monitored every quarter; Class 2 processes are monitored every other quarter. FIT Rate calculations for both classes are based on approximately one million device hours (at  $T_j = 125^\circ\text{C}$ ) per fab if the data is available. Processes that are four years old or less are monitored every quarter regardless of the FIT rate. Mature processes older than four years are monitored based on the FIT Rate. [Table 1-4](#) summarizes the classification criteria and monitoring frequency for both classes.

**Table 1-4: Monitoring Process Classes**

	<b>Class 1</b>	<b>Class 2</b>
Classification Criteria	Process Age $\leq$ 4 years or FIT > 26 (for FPGAs), 55 (for Flash PROM)	Process Age > 4 years and FIT < 26 (for FPGAs), 55 for Flash PROMs)
Monitor Frequency	4 times per year	2 times per year

The reliability tests used to monitor the wafer process are shown in [Table 1-5](#).

**Table 1-5: Tests Used to Monitor Wafer Processes**

Reliability Test	Condition	Duration	Lot Quantity	Sample Size per Process per Family per Quarter
HTOL	$T_j > 125^\circ\text{C}$ , $V_{DD}$ Max	1,000 hours	1	45
Data Retention Bake <sup>(1)</sup>	$T_A = 150^\circ\text{C}$	1,000 hours	1	45

**Notes:**

1. For CPLD and PROM products.

The package reliability monitor program takes into consideration the following factors:

- Package construction (wire-bond lead frame, wire-bond BGA, or flip chip)
- Factory location (assembly site, or wafer fabrication site)
- Substrate vendor
- Die size
- Technology maturity
- Past history

Based on these factors and availability, representative packages are drawn from inventory for the stress tests defined in Table 1-6. These tests are typically conducted on a quarterly basis, but the number of tests can be reduced or eliminated based on the maturity of the package technology, understanding of failure mechanisms, and their dependency on the stress test.

Table 1-6: Tests Used by the Reliability Package Monitor Program

Reliability Test	Stress Conditions	Stress Duration	Sample Size	Frequency
THB <sup>(1)</sup> or HAST <sup>(1)</sup>	85°C, 85% RH, V <sub>DD</sub>	1,000 hrs	45	WBLF <sup>(2)</sup> every even quarter WBBGA <sup>(3)</sup> every odd quarter Flip Chip <sup>(4)</sup> every quarter
	130°C, 85% RH, V <sub>DD</sub>	96 hrs		
	110°C, 85% RH, V <sub>DD</sub>	264 hrs		
Temperature cycling <sup>(1)(5)</sup>	-55°C to +125°C or -40°C to +125°C	1,000 cycles	45	WBLF every quarter WBBGA every quarter Flip Chip every quarter
Autoclave <sup>(1)(6)</sup> or Temperature humidity unbiased <sup>(1)(6)</sup> or HASTU <sup>(1)(6)</sup>	121°C, 100% RH	96 hrs	45	WBLF every odd quarter WBBGA every even quarter
	85°C, 85% RH	1,000 hrs		
	130°C, 85% RH or 110°C, 85% RH	96 hrs or 264 hrs		
HTS <sup>(7)</sup>	T <sub>A</sub> =150°C	1,000 hrs	45	WBLF every quarter WBBGA every quarter

**Notes:**

1. Package preconditioning is performed prior to THB, HAST, temperature cycling, autoclave, TH, and HASTU tests.
2. For matured WBLF packages (PLCCs, SOICs, and DIPs packages), reliability monitoring is performed once a year.
3. For matured WBBGA packages (S-BGA Cavity-down BGA), reliability monitoring is performed once a year.
4. For flip chip packages, THB testing is performed every quarter and replaces the need for temperature humidity testing.
5. For plastic QFP and BGA packages: -55°C to +125°C and 1,000 cycles; for flip chip packages: -55°C to +125°C and 1,000 cycles or 40°C/+125°C and 1,000 cycles.
6. Refer to the device-specific qualification report for complete autoclave, temperature humidity, and HASTU reliability test data.
7. HTS stress is not applicable with flip chip package because the technology has no wire-bond IMC interface degradation.

## ESD and Latch-up Summary

ESD results are obtained according to specifications ANSI/ESDA/JEDEC JS-001-2010 and JEDEC JESD22-C101. Latch-up results are obtained by using specification EIA/JESD78. ESD tests are performed at 25°C. In general, the latch-up data for newer products such as Zynq-7000 SoCs, 7 series, Virtex®-4, Virtex®-5, Virtex®-6, Spartan®-3, and Spartan®-6 devices are collected at 125°C unless specified otherwise.

ESD and latch-up data are summarized by family in these tables:

- Charge device model passing voltage for VBATT pin is 300V.
- If an internal AC coupling capacitor is used in the GTP receiver input (RX) pin, the CDM level is 150V. Compliance to ANSI/ESD S20.20 (ESD Association standard for the electrostatic discharge control program) is necessary.
- The D\_IN and CS\_B pins on XC5VLX220 and XC5VLX220T devices pass at 150 mA.

## Failure Rate Determination

The failure rate is typically defined in FIT units. One FIT equals 1 failure per 1 billion device hours. For example, 5 failures expected out of 1 million components operating for 1,000 hours have a failure rate of 5 FIT. The following is the failure rate calculation method:

$$\text{Failure Rate} = \frac{x^2 10^9}{2(\text{No. of Devices})(\text{No. of Hours})(\text{Acc. Factor})} \quad \text{Equation 1-1}$$

where:

$x^2$  = Chi-squared value at a desired confidence level and  $(2f + 2)$  degrees of freedom, where  $f$  is the number of failures.

The acceleration factor is calculated using the Arrhenius relationship:

$$A = \exp\left\{\frac{E_a}{k} \cdot \left(\frac{1}{T_{J1}} - \frac{1}{T_{J2}}\right)\right\} \quad \text{Equation 1-2}$$

where:

$E_a$  = Thermal activation energy (0.7eV is assumed and used in failure rate calculation except EPROM in which 0.58 eV is used).

$A$  = Acceleration factor

$k$  = Boltzmann's constant,  $8.617164 \times 10^{-5}$  eV/K

$T_{J1}$  = Use junction temperature in Kelvin ( $K = ^\circ C + 273.16$ )

$T_{J2}$  = Stress junction temperature in Kelvin ( $K = ^\circ C + 273.16$ )

## SEU and Soft Error Rate Measurements

Table 1-19 and Table 1-20 show the soft error rates caused by single event upsets (SEUs) affecting memory cells used as configuration memory and block RAM. Neutron cross-sections are determined from LANSCE beam testing according to JESD89A/89-3A. Soft error rates (in FIT/Mb) are determined from real-time (system level) measurements in various locations and altitudes and corrected for New York City, according to JESD89A/89-1A. Also refer to *Continuing Experiments of Atmospheric Neutron Effects on Deep Submicron Integrated Circuits* (WP286) [Ref 2]. All data is current as of the date of this report.

An upset in any configuration bit does not create a soft functional error per se. The bit has to be one that is critical to the function in order for a soft functional error to occur. The number of unused bits and non-critical bits reduces the effective soft error rate by what is known as the device vulnerability factor (DVF). The DVF for a typical design is 5% (one in 20 upsets, on average, cause a functional soft error). In the worst case, the DVF is never larger than one in ten, or never more than 10% of the upsets cause a soft functional error. Therefore, the functional soft error rate of a design running in a Xilinx FPGA is far lower than what is predicted by calculation from the data in Table 1-19 and Table 1-20. The significant factor contributing to low DVF is that most FPGA routing resources are unused within any particular implementation.

Xilinx offers a significant portfolio of SEU analysis and mitigation solutions to help you understand and interpret soft error rates and manage SEU rates in any given design. Consult your Xilinx sales and field support for assistance in understanding these capabilities, and visit our [Single Event Upsets website](#) to obtain the Xilinx SEU Estimator tool for modeling device-level SEU rates based on operating environment and the data in Table 1-19 and Table 1-20. The Xilinx SEU Estimator tool models total SEU rate in terrestrial environments by scaling the real-time data based on operating environment and adding the alpha particle data.

In [Table 1-19](#) and [Table 1-20](#), Tech Node is technology node, CRAM is configuration RAM, and BRAM is block RAM. The data in these tables is not a specification but is for reference only, under the stated conditions for each experiment.

### High-Temperature Operating Life (HTOL) Test

The HTOL test is conducted under the conditions of  $T_J \geq 125^\circ\text{C}$  temperature, maximum  $V_{DD}$  and either dynamic or static operation. The FIT failure rate calculation in the following tables is based on the assumption of 0.7 eV activation energy and 60% confidence level (CL).
